Review: Condition Codes

Single bit registers

CF Carry Flag (for unsigned) **SF** Sign Flag (for signed)

ZF Zero Flag **OF** Overflow Flag (for signed)

jX and SetX instructions

jX	Condition	Description
<code>jmp</code>	1	Unconditional
<code>je</code>	<code>ZF</code>	Equal / Zero
<code>jne</code>	$\sim ZF$	Not Equal / Not Zero
<code>js</code>	<code>SF</code>	Negative
<code>jns</code>	$\sim SF$	Nonnegative
<code>jg</code>	$\sim (SF \wedge OF) \ \& \ \sim ZF$	Greater (Signed)
<code>jge</code>	$\sim (SF \wedge OF)$	Greater or Equal (Signed)
<code>jl</code>	$(SF \wedge OF)$	Less (Signed)
<code>jle</code>	$(SF \wedge OF) \ ZF$	Less or Equal (Signed)
<code>ja</code>	$\sim CF \ \& \ \sim ZF$	Above (unsigned)
<code>jb</code>	<code>CF</code>	Below (unsigned)

SetX	Condition	Description
<code>sete</code>	<code>ZF</code>	Equal / Zero
<code>setne</code>	$\sim ZF$	Not Equal / Not Zero
<code>sets</code>	<code>SF</code>	Negative
<code>setns</code>	$\sim SF$	Nonnegative
<code>setg</code>	$\sim (SF \wedge OF) \ \& \ \sim ZF$	Greater (Signed)
<code>setge</code>	$\sim (SF \wedge OF)$	Greater or Equal (Signed)
<code>setl</code>	$(SF \wedge OF)$	Less (Signed)
<code>setle</code>	$(SF \wedge OF) \ ZF$	Less or Equal (Signed)
<code>seta</code>	$\sim CF \ \& \ \sim ZF$	Above (unsigned)
<code>setb</code>	<code>CF</code>	Below (unsigned)

Review : Machine Level Programming

C Control

if-then-else

do-while

while, for

switch

Assembler Control

Conditional jump

Conditional move

Indirect jump (via jump tables)

Compiler generates code sequence to implement more complex control

Standard Techniques

Loops converted to do-while or jump-to-middle form

Large switch statements use jump tables

Sparse switch statements may use decision trees (if-elseif-elseif-else)

Review : for loop (x86)

Example

```
int loop (int x, int y)
{
    int result;
    for (result=0; x>y; result++) {
        x--;
        y++;
    }
    result++;
    return result;
}
```

```
loop:
    pushl %ebp
    movl %esp,%ebp
    movl 8(%ebp),%ecx
    movl 12(%ebp),%edx
    xorl %eax,%eax
    cmpl %edx,%ecx
    jle .L4

.L6:
    decl %ecx
    incl %edx
    incl %eax
    cmpl %edx,%ecx
    jg .L6

.L4:
    incl %eax
    movl %ebp,%esp
    popl %ebp
    ret
```

Homework #4

Patch a binary

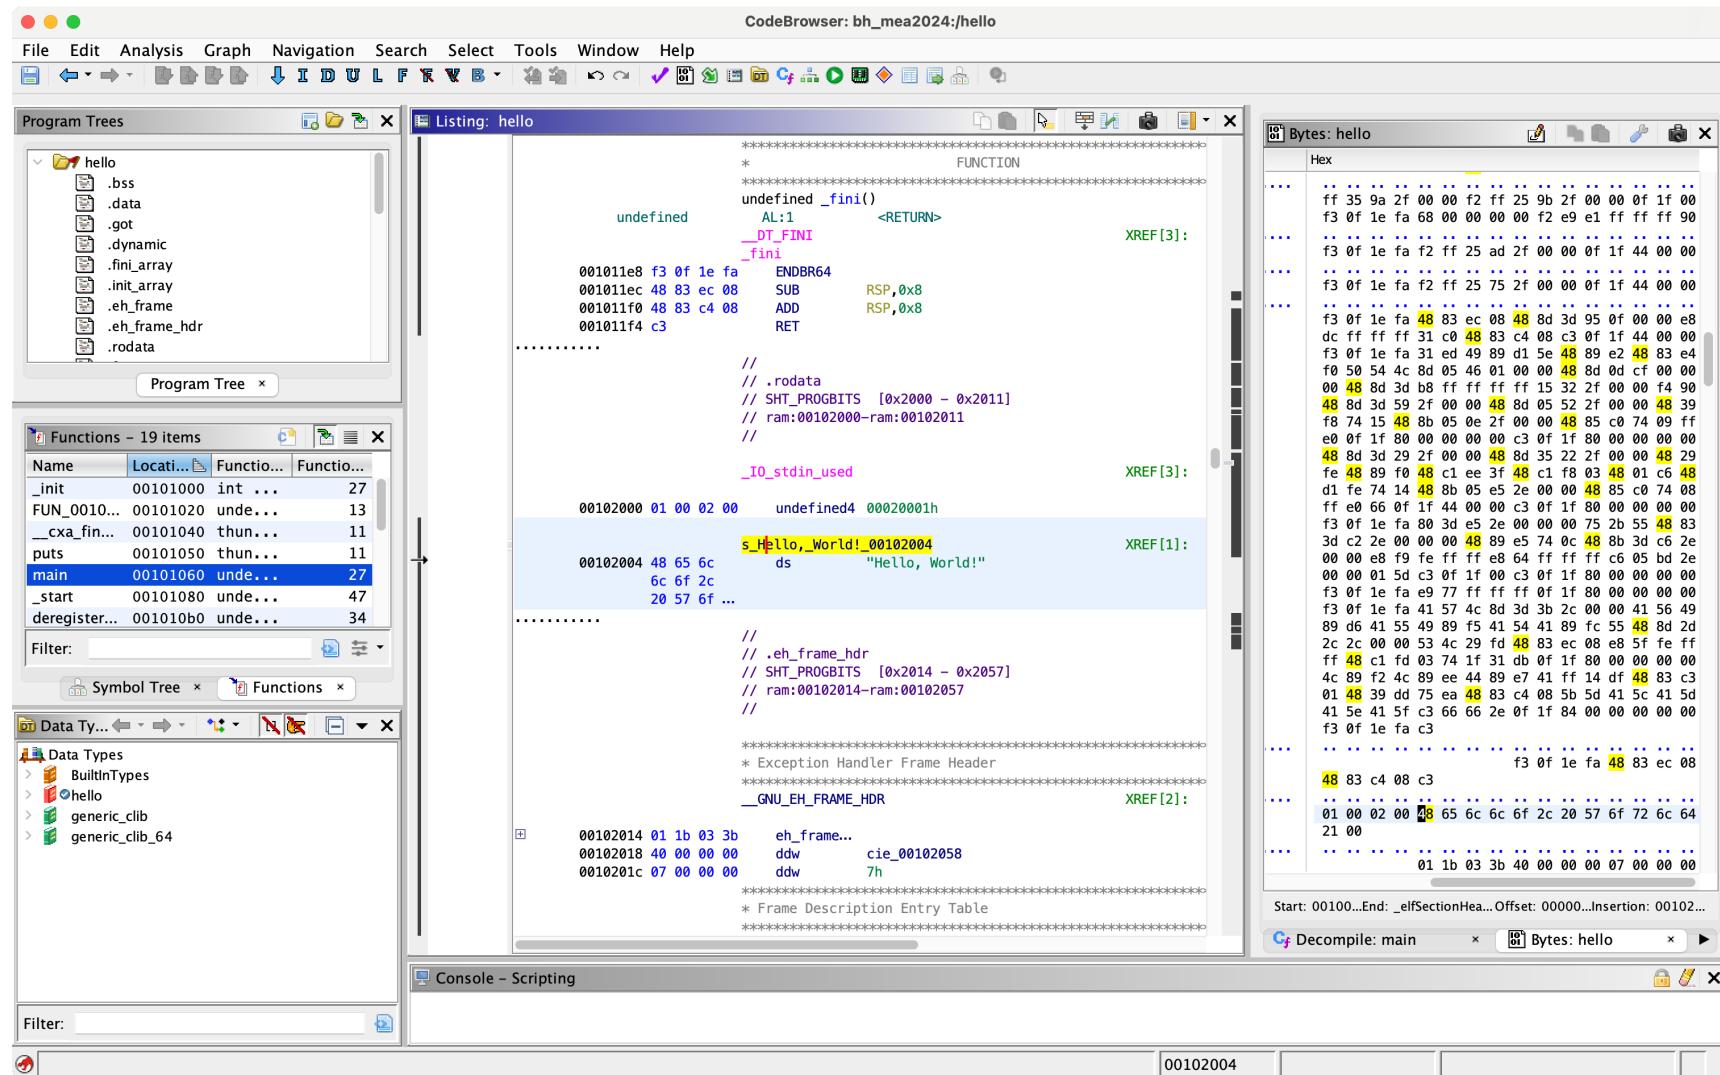

- Homework #04
 - Overview
 - **Released date:** 10/4 (Fri.)
 - **Due date:** 10/11 (Fri.)
 - **Where to submit:** to e-class (<http://eclass.seoultech.ac.kr>)
 - Late submission is not allowed.
 - **Assigned score:** 1 points

Decompile `hello` binary and change the string value to print your STUDENT ID

- Submissions
 - Explain how to change the string in the bss section.
 - Captured images to show the result

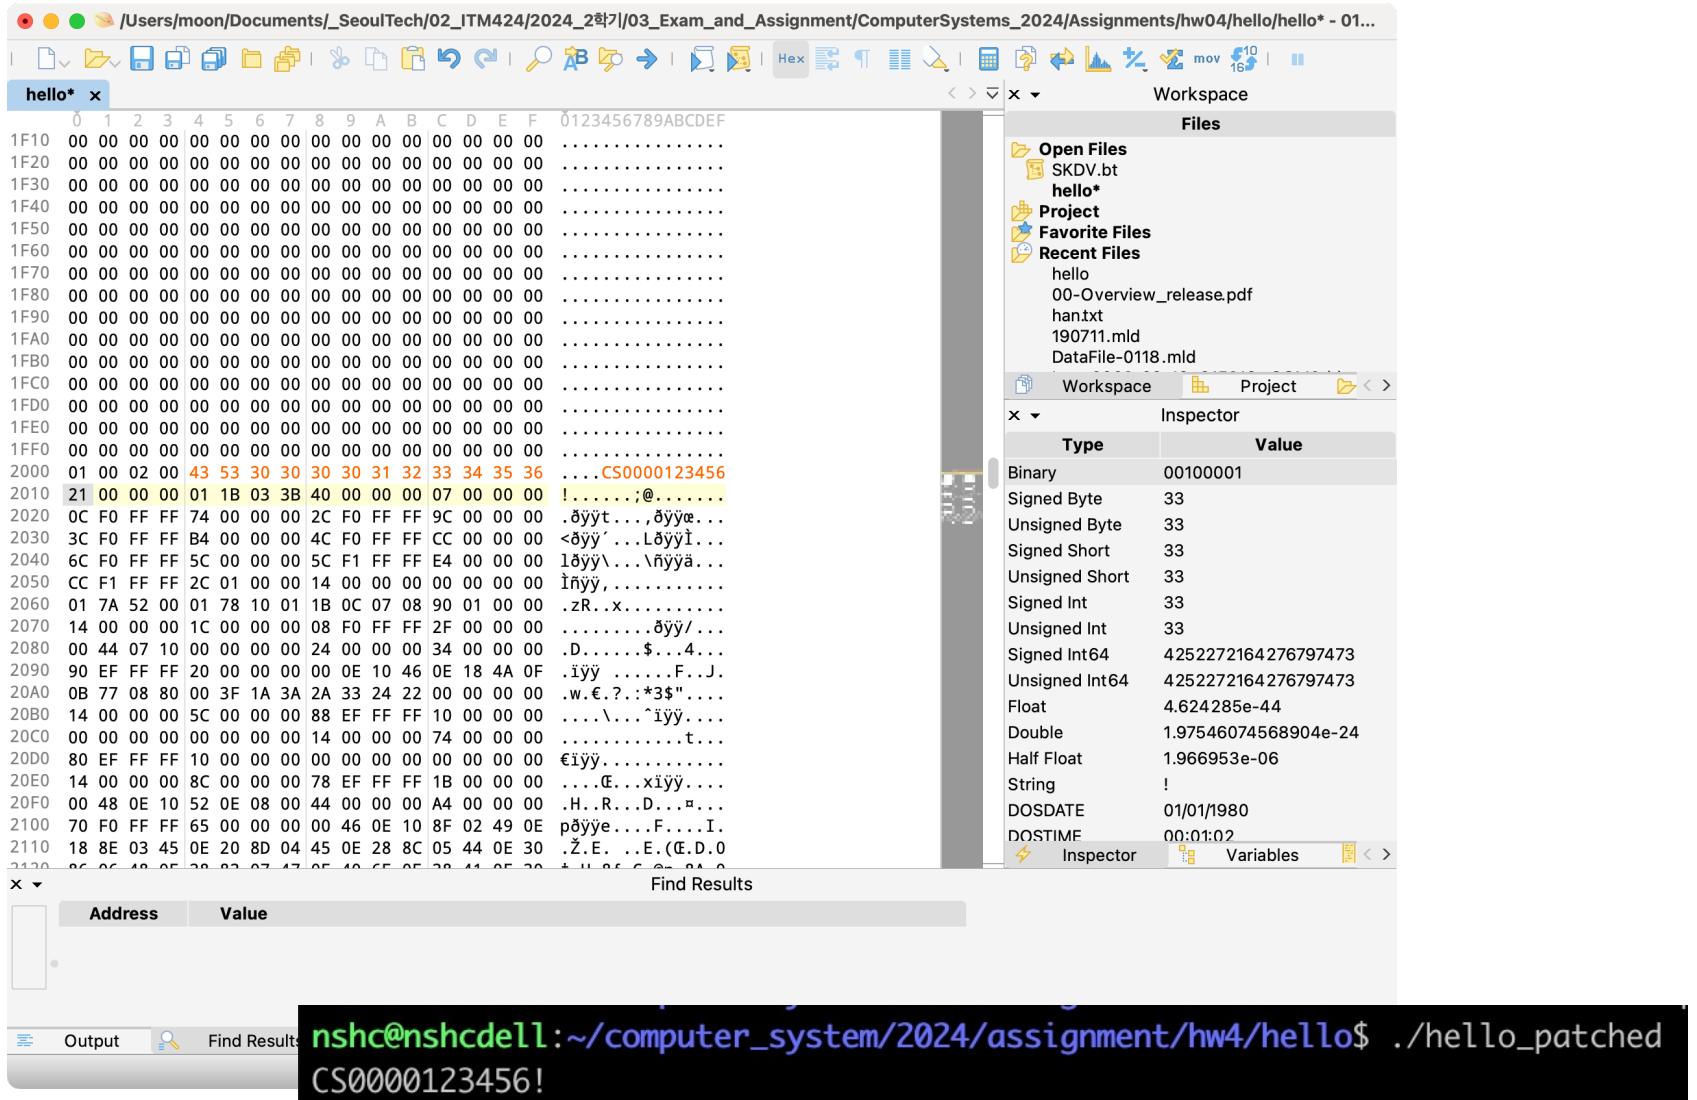

Homework #4

Patch a binary

Homework #4

Patch a binary

The screenshot shows the Immunity Debugger interface with the assembly view open. The assembly window displays memory starting at address 1F10, showing various instructions and their hex values. A specific instruction at address 2000 is highlighted in orange, containing the value CS000123456. The Immunity Debugger's sidebar includes a 'Workspace' panel showing open files like 'SKDV.bt' and 'hello*', and an 'Inspector' panel displaying various memory variables and their values.

x86-64 Stack

**Region of memory managed
with stack discipline**

Memory viewed as array of bytes.

Different regions have different purposes.

(Like ABI, a policy decision)

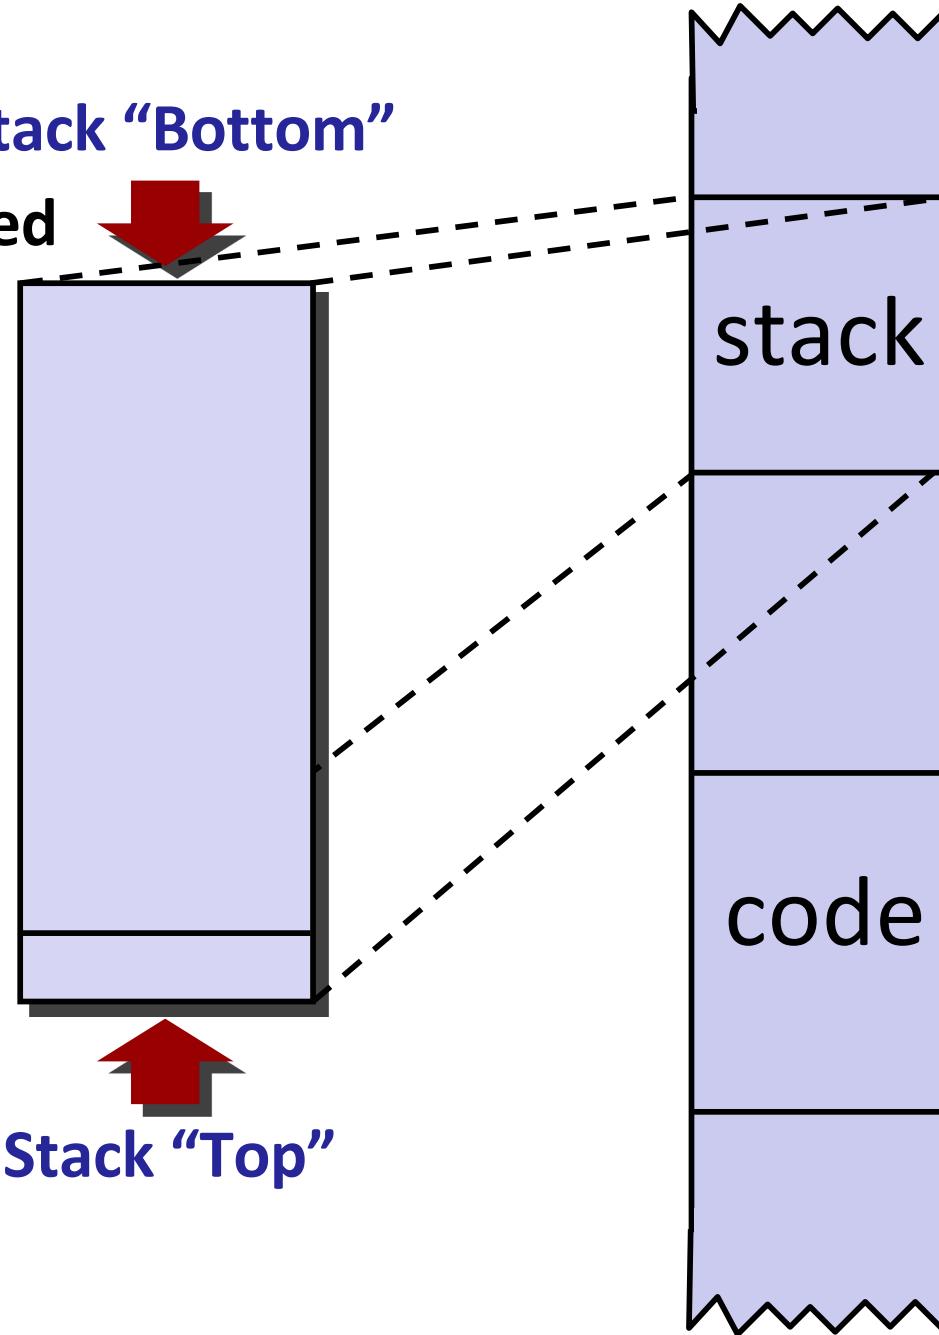

x86-64 Stack

Region of memory managed
with stack discipline

Stack “Bottom”

Stack Pointer: %rsp →

Stack “Top”

x86-64 Stack

**Region of memory managed
with stack discipline**

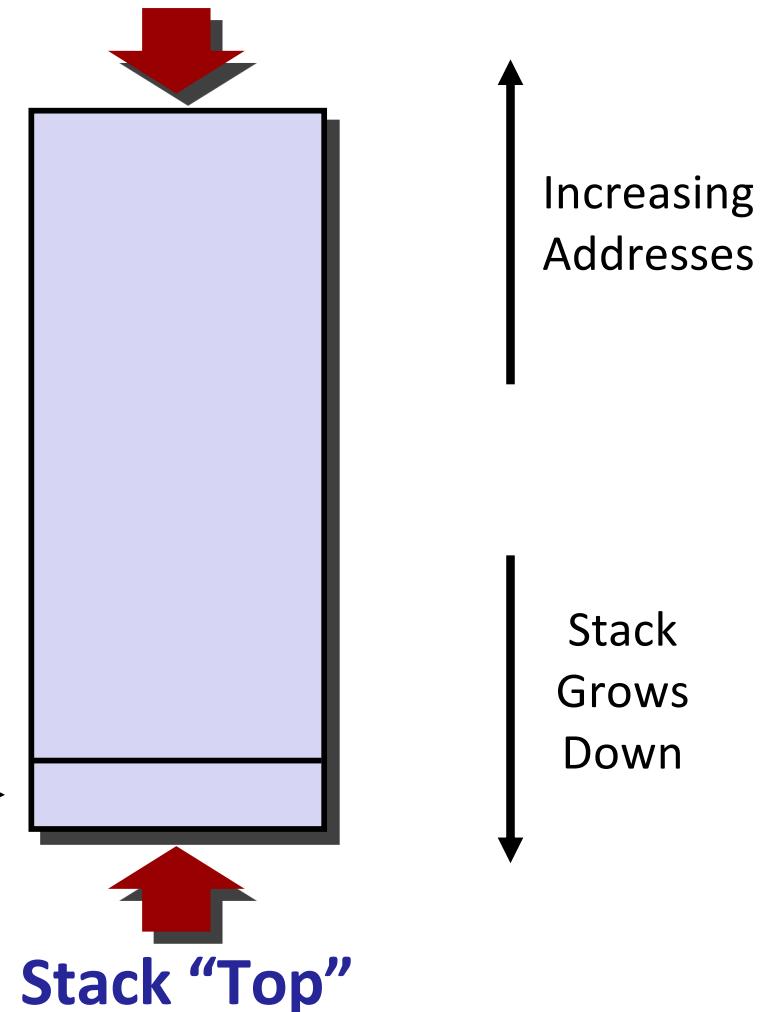

Grows toward lower addresses

**Register `%rsp` contains
lowest stack address**

address of “top” element

Stack Pointer: `%rsp` →

Stack “Bottom”

x86-64 Stack: Push

pushq Src

Fetch operand at *Src*

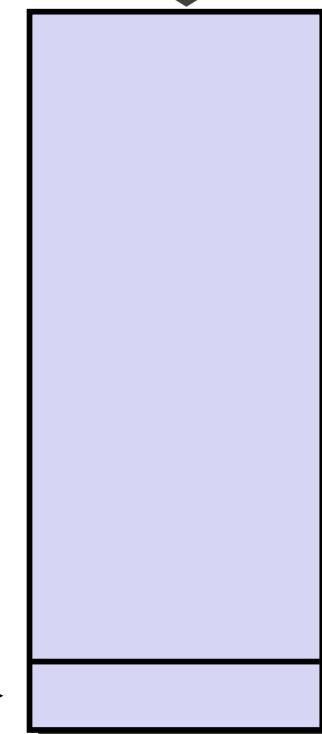

val

Decrement **%rsp** by 8

Write operand at address given by **%rsp**

Stack Pointer: →
%rsp

Stack “Bottom”

Stack “Top”

x86-64 Stack: Push

pushq Src

Fetch operand at *Src*

val

Decrement **%rsp** by 8

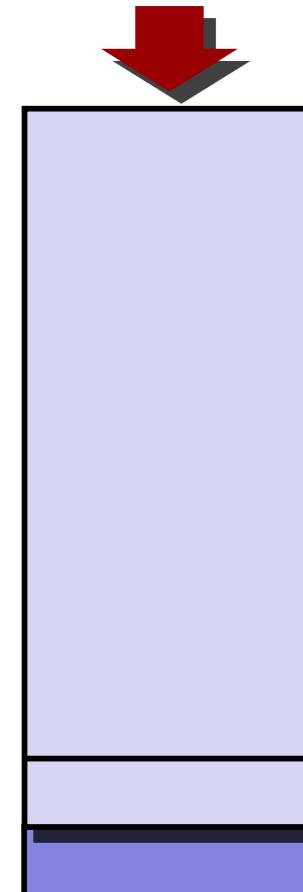

Write operand at address given by **%rsp**

Stack Pointer:

%rsp

 -8

Stack “Bottom”

Stack “Top”

x86-64 Stack: Pop

popq Dest

Read value at address given by `%rsp`

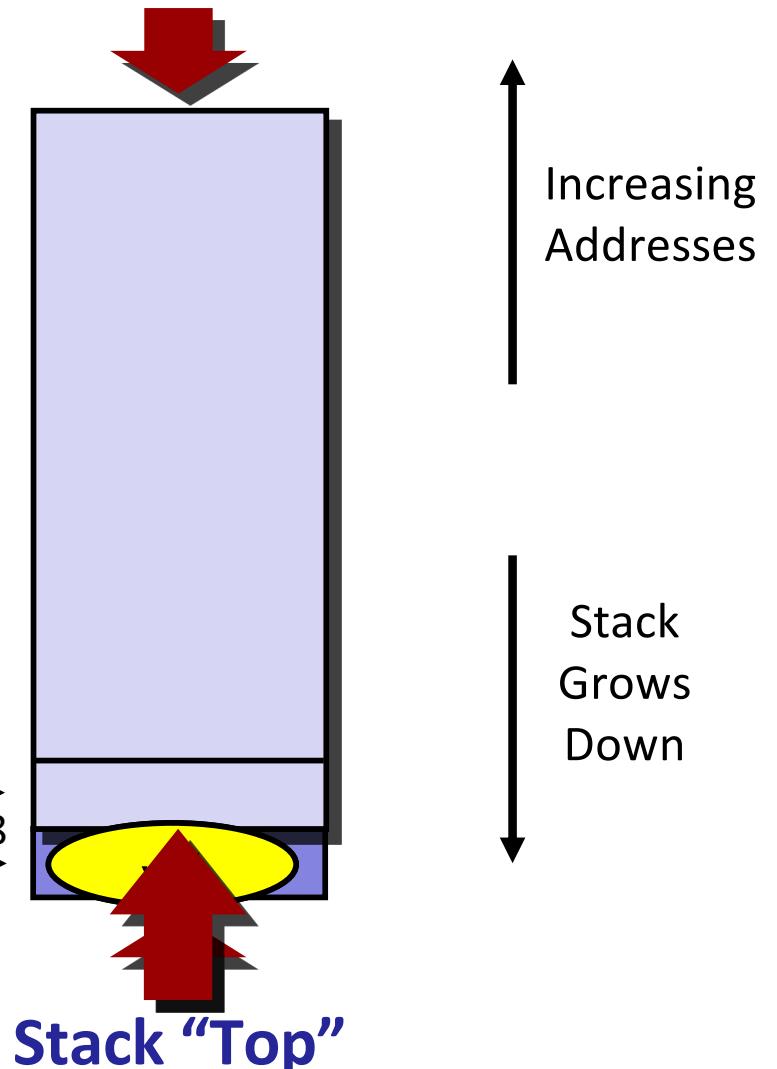

Increment `%rsp` by 8

Store value at Dest (usually a register)

Value is **copied**; it remains
in memory at old `%rsp`

Stack Pointer:
`%rsp` 

Stack “Bottom”

Stack “Top”

Code Examples

```
void multstore(long x, long y, long *dest)
{
    long t = mult2(x, y);
    *dest = t;
}
```

000000000400540 <multstore>:

400540:	push	%rbx	# Save %rbx
400541:	mov	%rdx,%rbx	# Save dest
400544:	call	400550 <mult2>	# mult2(x,y)
400549:	mov	%rax, (%rbx)	# Save at dest
40054c:	pop	%rbx	# Restore %rbx
40054d:	ret		# Return

```
long mult2(long a, long b)
{
    long s = a * b;
    return s;
}
```

000000000400550 <mult2>:

400550:	mov	%rdi,%rax	# a
400553:	imul	%rsi,%rax	# a * b
400557:	ret		# Return

Procedure Control Flow

Use stack to support procedure call and return

Procedure call: `call label`

Push return address on stack

Jump to *label*

Return address:

Address of the next instruction right after call

Example from disassembly

Procedure return: `ret`

Pop address from stack

Jump to address

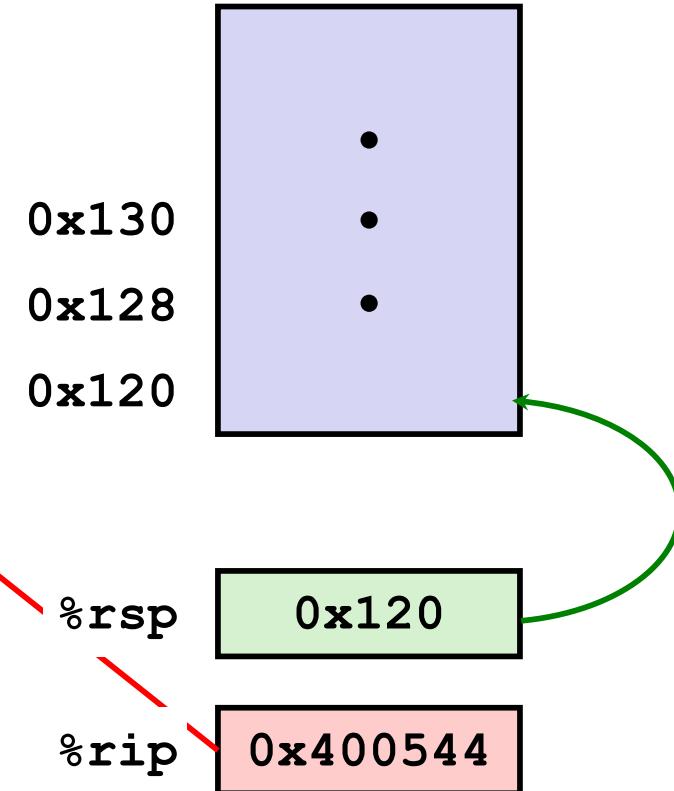

These instructions are sometimes printed with a `q` suffix

This is just to remind you that you're looking at 64-bit code

Control Flow Example #1

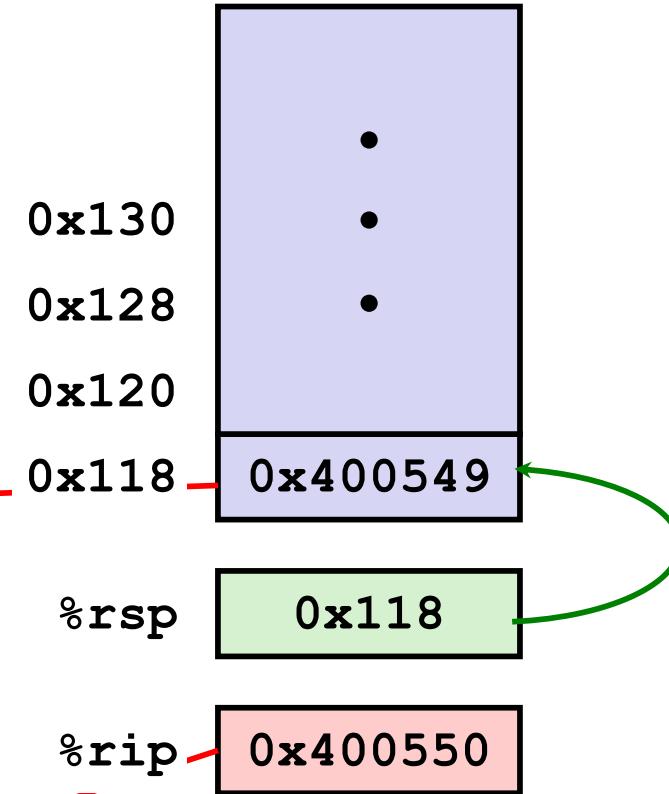

```
0000000000400540 <multstore>:  
.  
. .  
400544: call    400550 <mult2>  
400549: mov     %rax, (%rbx)  
. .
```

```
0000000000400550 <mult2>:  
400550: mov     %rdi,%rax  
. .  
400557: ret
```

Control Flow Example #2

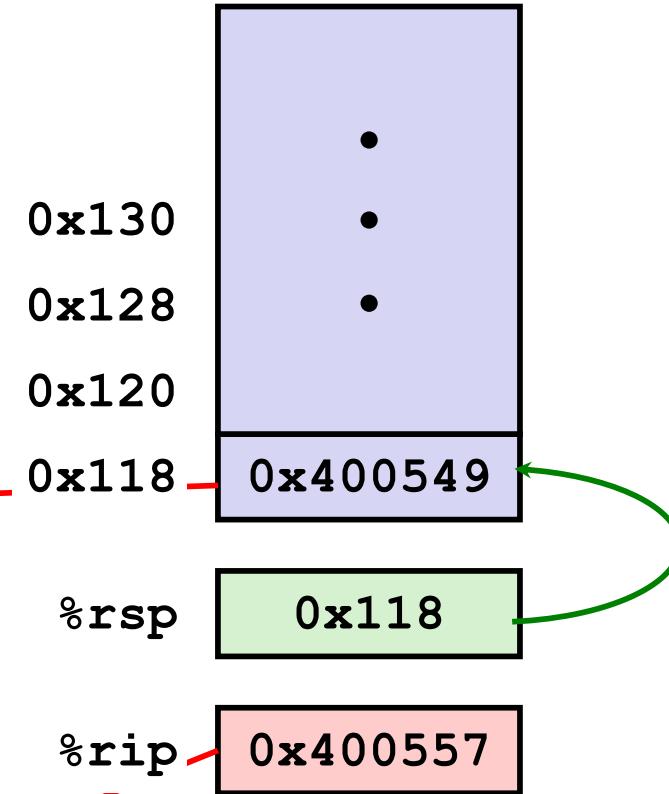

```
0000000000400540 <multstore>:  
.  
. .  
400544: call    400550 <mult2>  
400549: mov     %rax, (%rbx) ←
```

```
0000000000400550 <mult2>:  
400550: mov     %rdi,%rax ←  
. .  
400557: ret
```

Control Flow Example #3

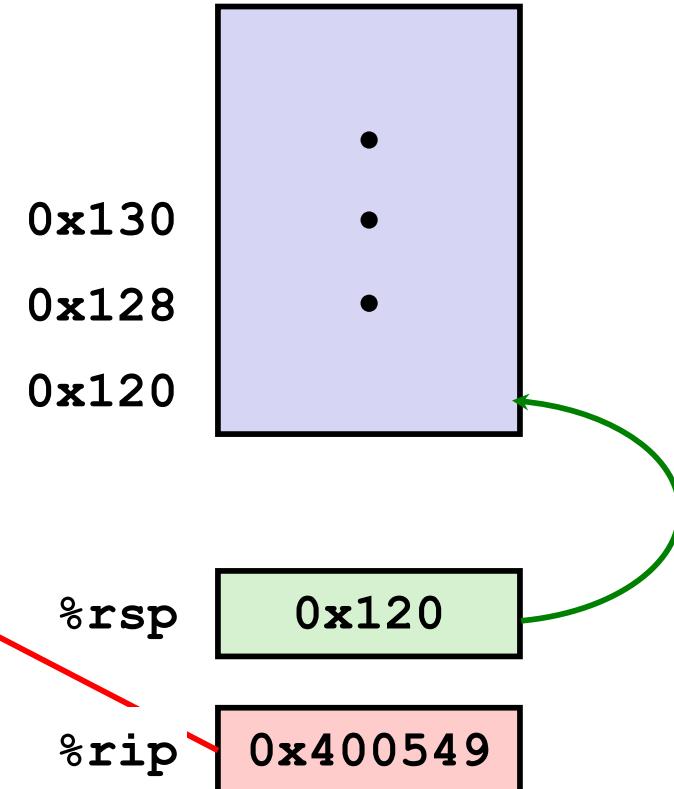

```
0000000000400540 <multstore>:  
.  
. .  
400544: call    400550 <mult2>  
400549: mov     %rax, (%rbx) ←
```

```
0000000000400550 <mult2>:  
400550: mov     %rdi,%rax  
. .  
400557: ret ←
```

Control Flow Example #4

```
0000000000400540 <multstore>:  
.  
. .  
400544: call    400550 <mult2>  
400549: mov     %rax, (%rbx)  
. .
```

```
0000000000400550 <mult2>:  
400550: mov     %rdi,%rax  
. .  
400557: ret
```

Data Flow Examples

```
void multstore
    (long x, long y, long *dest)
{
    long t = mult2(x, y);
    *dest = t;
}
```

```
0000000000400540 <multstore>:
# x in %rdi, y in %rsi, dest in %rdx
• • •
400541: mov    %rdx,%rbx          # Save dest
400544: call   400550 <mult2>      # mult2(x,y)
# t in %rax
400549: mov    %rax,(%rbx)        # Save at dest
• • •
```

```
long mult2
    (long a, long b)
{
    long s = a * b;
    return s;
}
```

```
0000000000400550 <mult2>:
# a in %rdi, b in %rsi
400550: mov    %rdi,%rax          # a
400553: imul   %rsi,%rax          # a * b
# s in %rax
400557: ret                   # Return
```

Procedure Data Flow (x86)

Example

```
/* copy string x to buf */
void foo(char *x) {
    int buf[1];
    strcpy((char *)buf, x);
}

void callfoo() {
    foo("abcdefghijklm");
}
```

Procedure Call

Example

```
/* copy string to buf */
void foo(char *buf)
{
    int buflen = strlen(buf);
    strcpy(buf, "abcde");
}

void callfoo()
{
    foo("abcde");
}
```

Procedure Data Flow (x86)

Example

```
/* copy string x to buf */
void foo(char *x) {
    int buf[1];
    strcpy((char *)buf, x);
}

void callfoo() {
    foo("abcdefghijklm");
}
```

buf[0] = 0x _____
buf[1] = 0x _____
buf[2] = 0x _____

Procedure Data Flow (x86)

Example

```
/* copy string x to buf */
void foo(char *x) {
    int buf[1];
    strcpy((char *)buf, x);
}

void callfoo() {
    foo("abcdefghijklm");
}
```

buf[0] = 0x64636261
buf[1] = 0x68676665 **saved ebp**
buf[2] = 0x08040069 **return address**

- Passing data

- Managing local data

Arrays

- One-dimensional

- Multi-dimensional (nested)

- Multi-level

Structures

- Allocation

- Access

- Alignment

Stack-Based Languages

Languages that support recursion

e.g., C, Pascal, Java

Code must be “*Reentrant*”

Multiple simultaneous instantiations of single procedure

Need some place to store state of each instantiation

Arguments

Local variables

Return pointer

Stack discipline

State for given procedure needed for limited time

From when called to when return

Callee returns before caller does

Stack allocated in *Frames*

state for single procedure instantiation

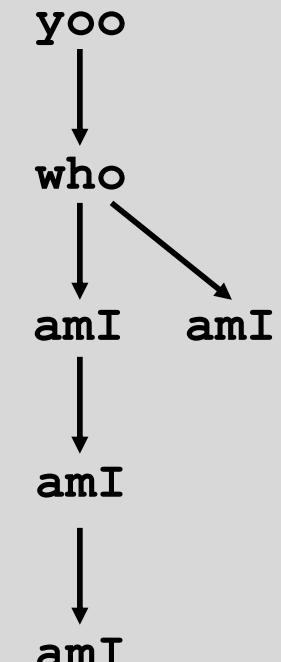

Call Chain Example

```
yoo (...)  
{  
    •  
    •  
    who () ;  
    •  
    •  
}
```

```
who (...)  
{  
    • • •  
    amI () ;  
    • • •  
    amI () ;  
    • • •  
}
```

```
amI (...)  
{  
    •  
    •  
    amI () ;  
    •  
    •  
}
```

Example Call Chain

Procedure **amI ()** is recursive

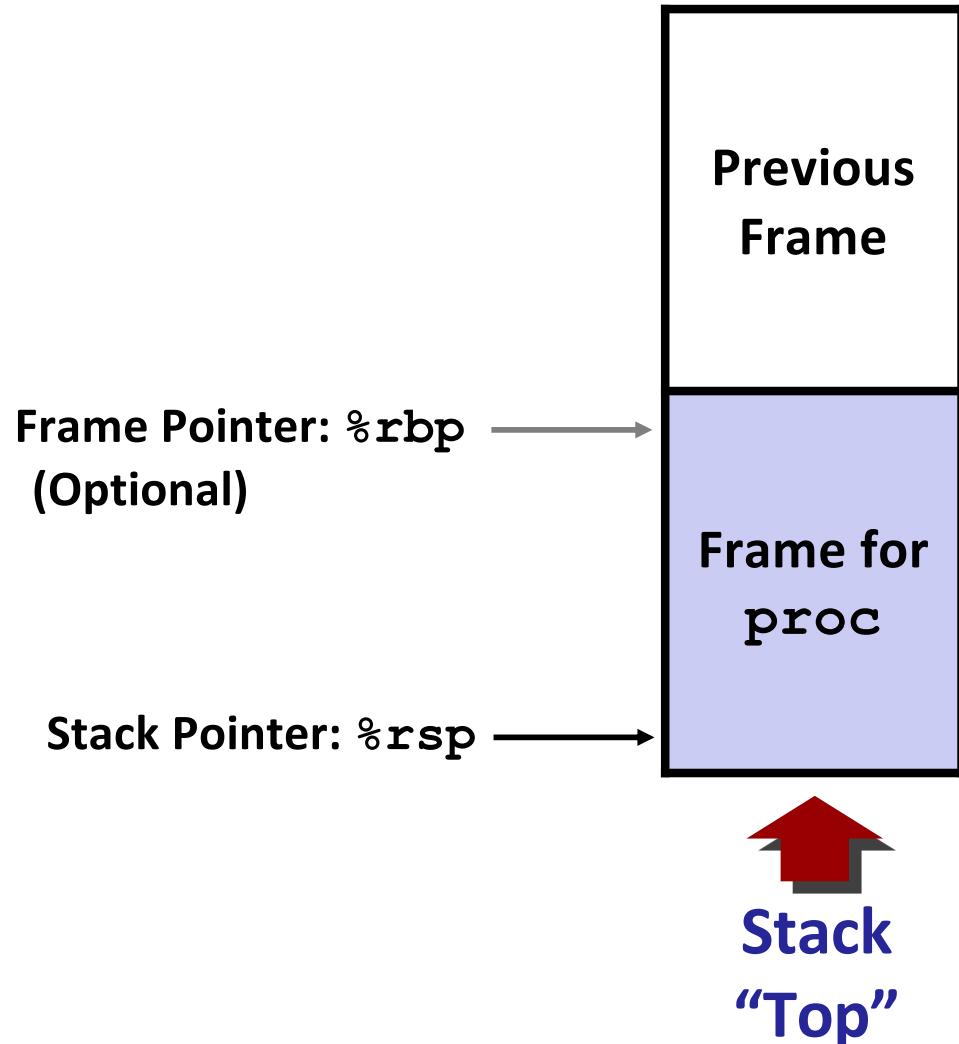

Stack Frames

Contents

- Return information
- Local storage (if needed)
- Temporary space (if needed)

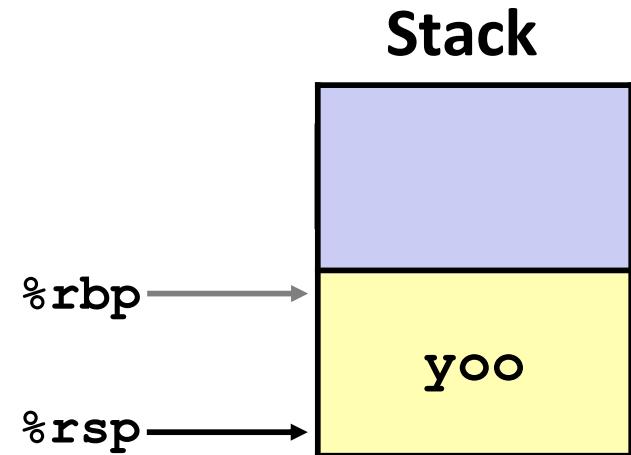

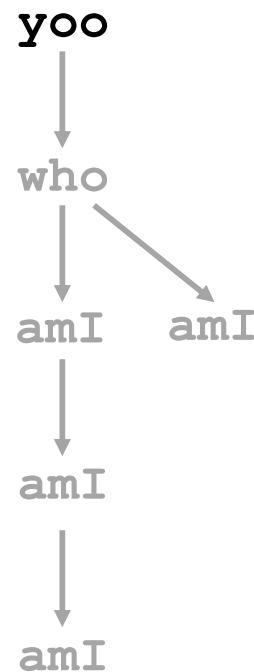

Management

- Space allocated when enter procedure
 - “Set-up” code
 - Includes push by **call** instruction
 - Deallocated when return
 - “Finish” code
 - Includes pop by **ret** instruction

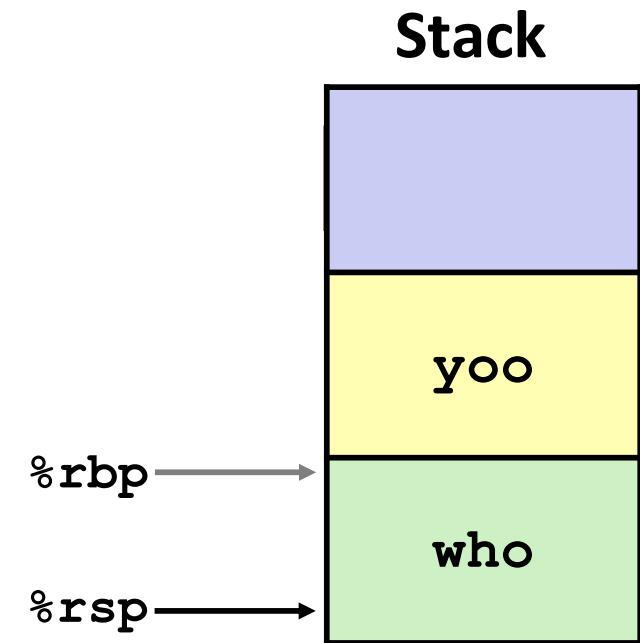

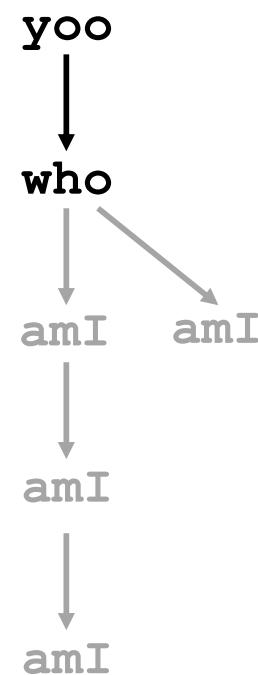

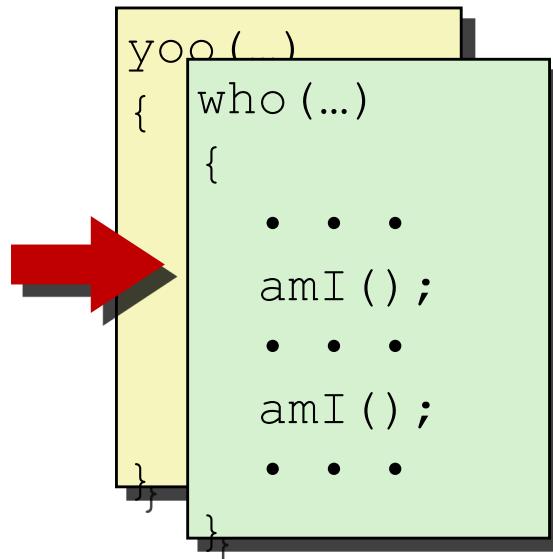

Example

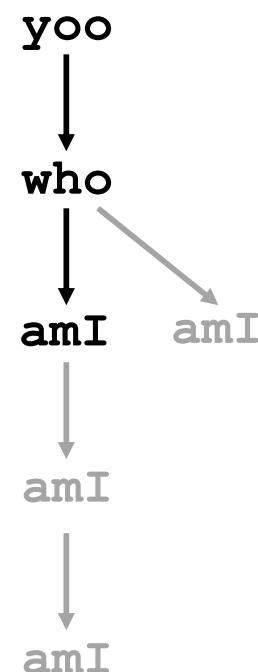

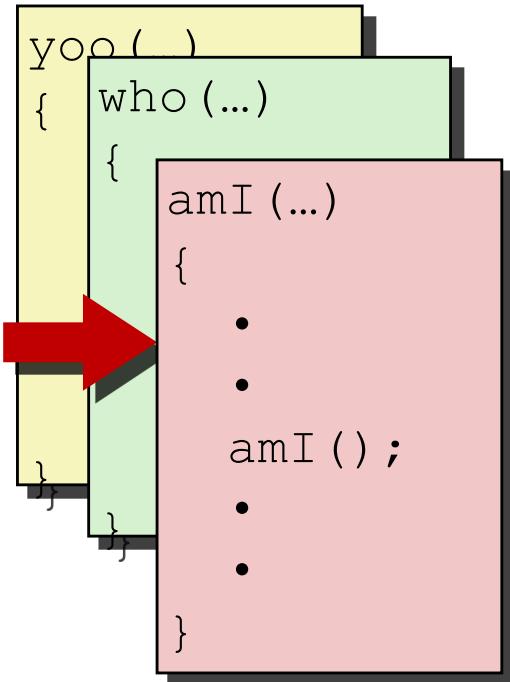

```
yoo (...)  
{  
    •  
    •  
    who () ;  
    •  
    •  
}
```

Example

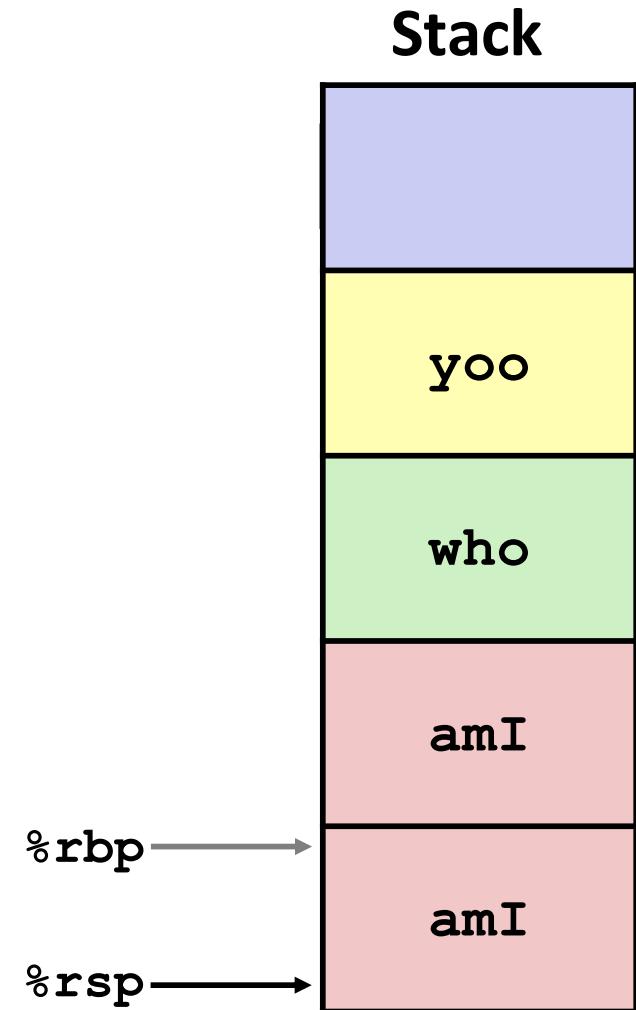

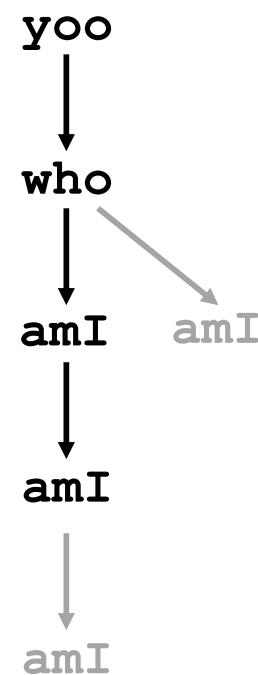

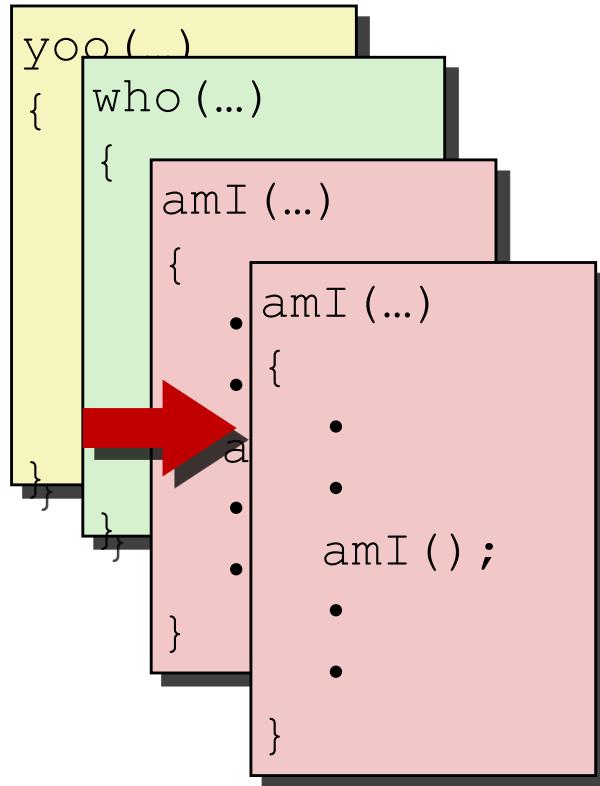

Example

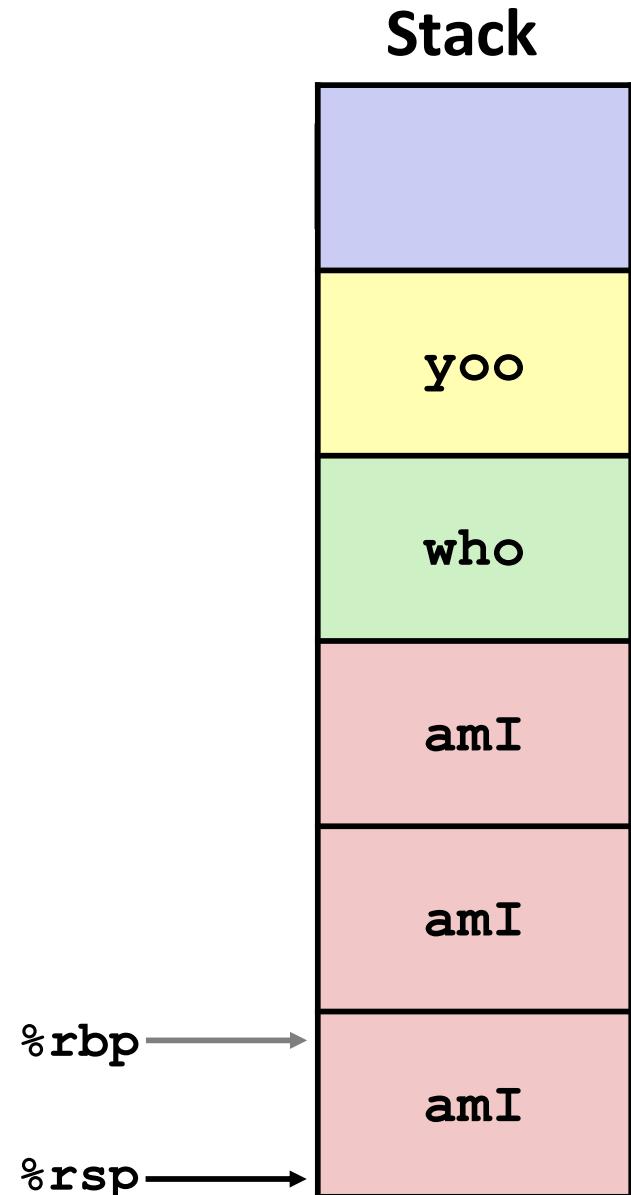

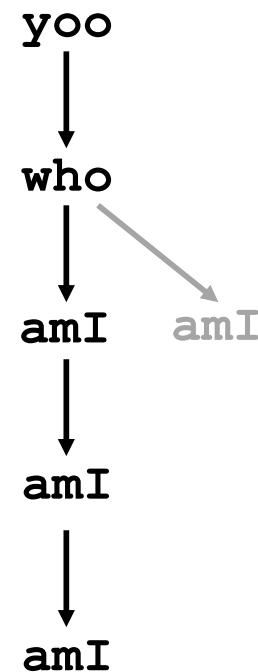

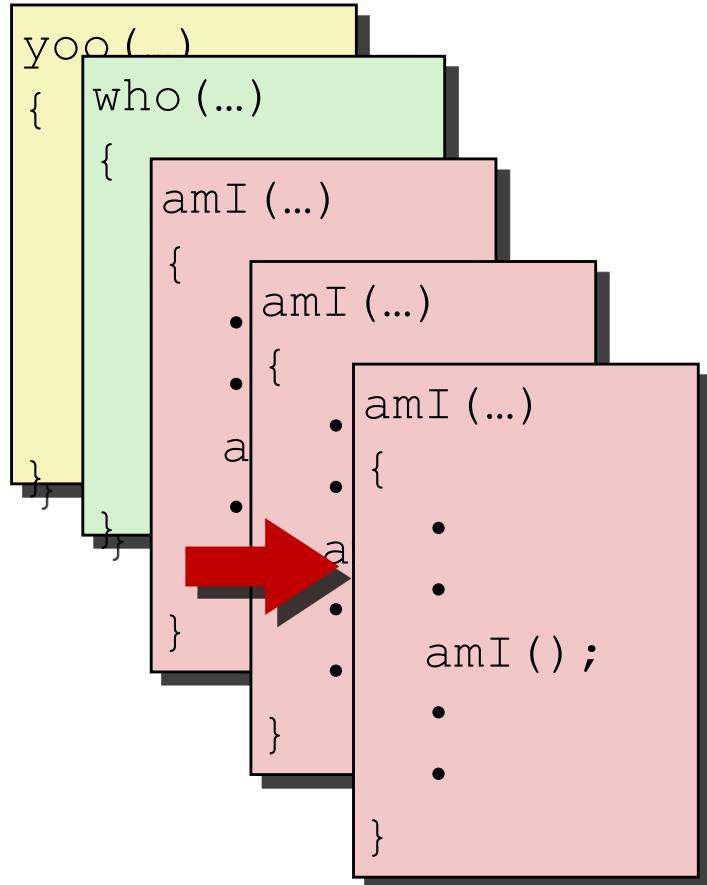

Stack

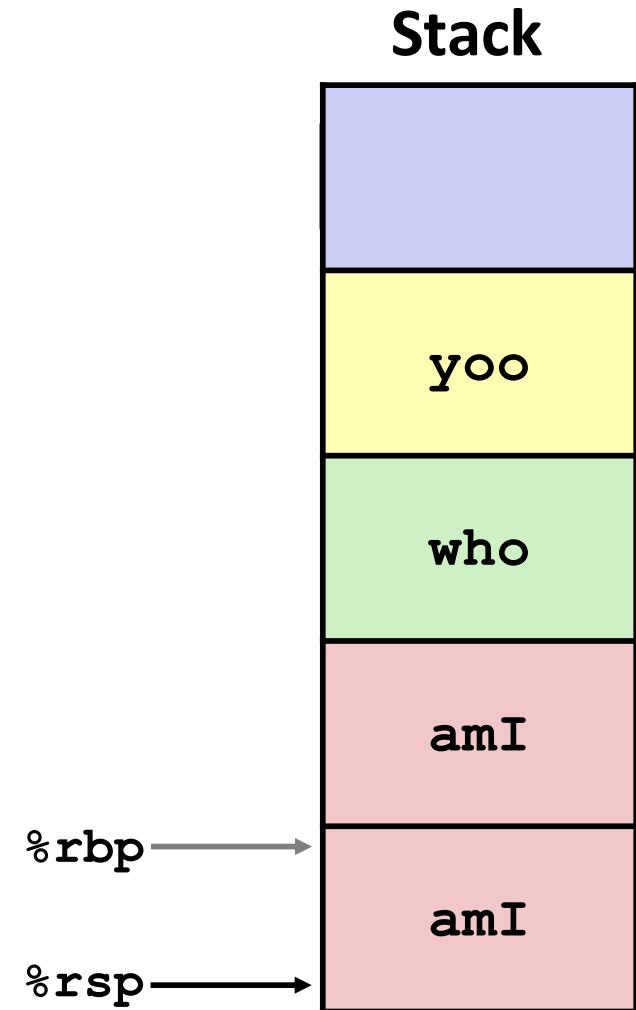

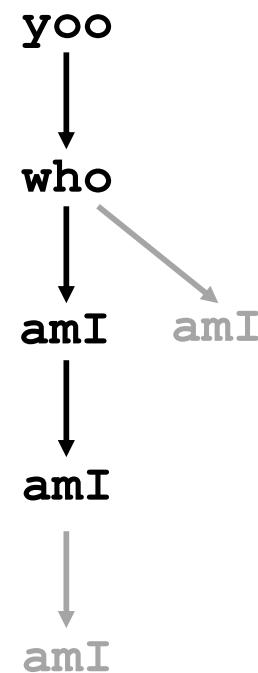

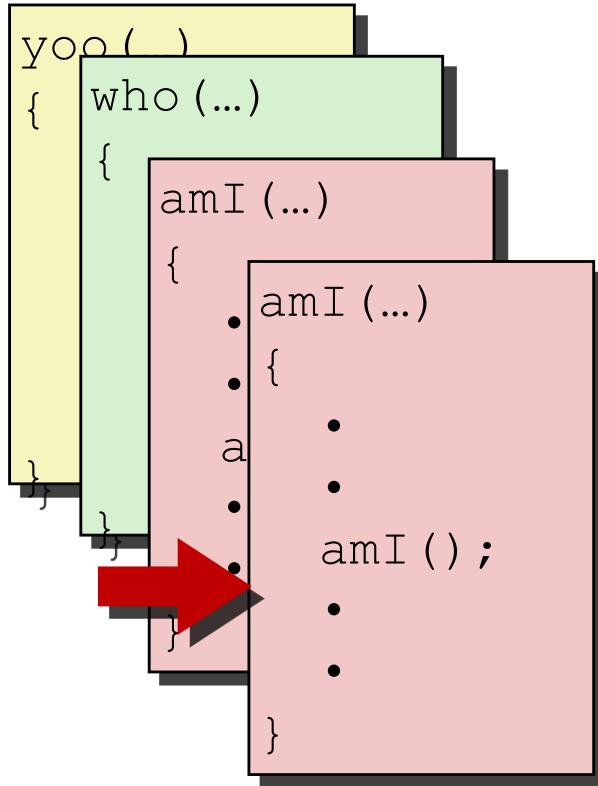

Example

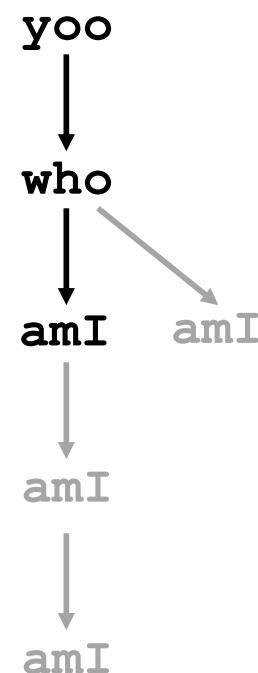

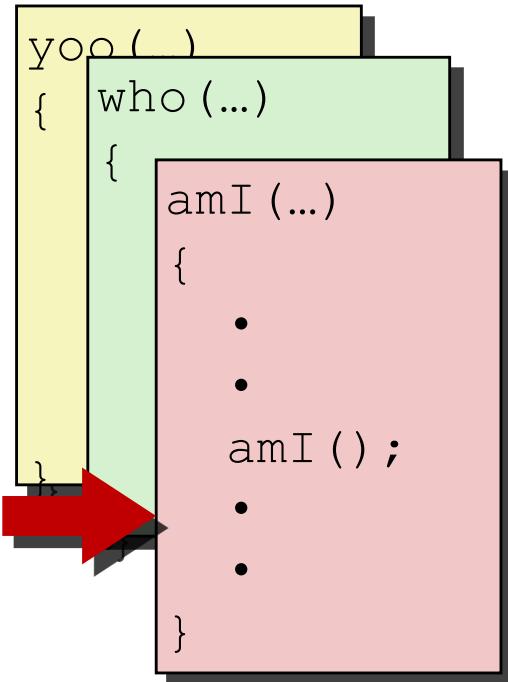

Example

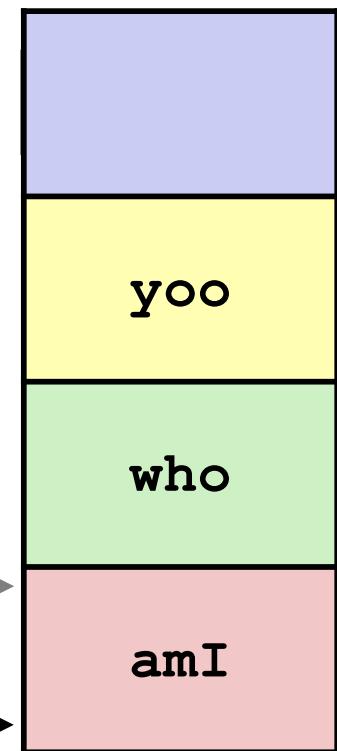

Example

Example

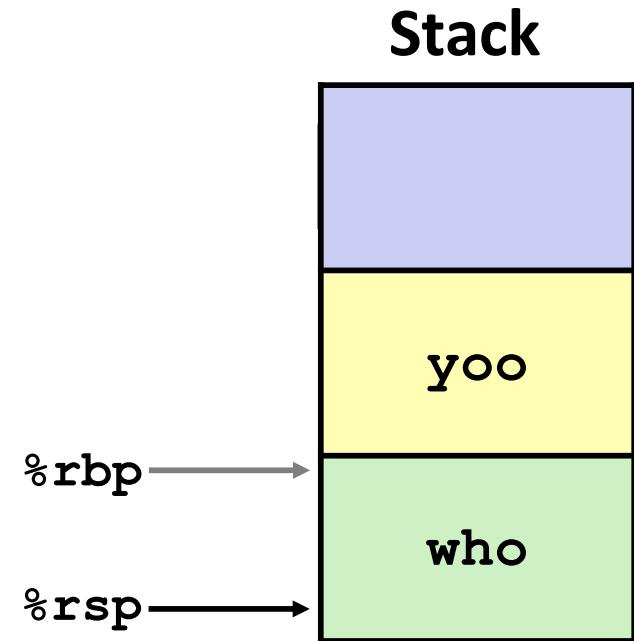

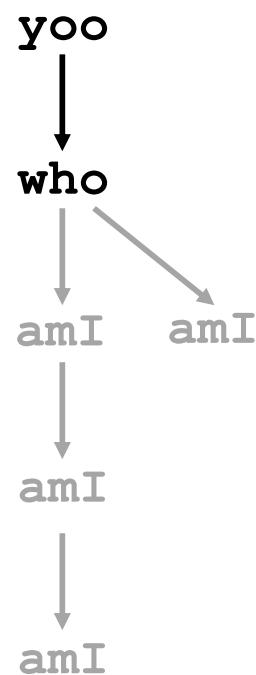

Stack

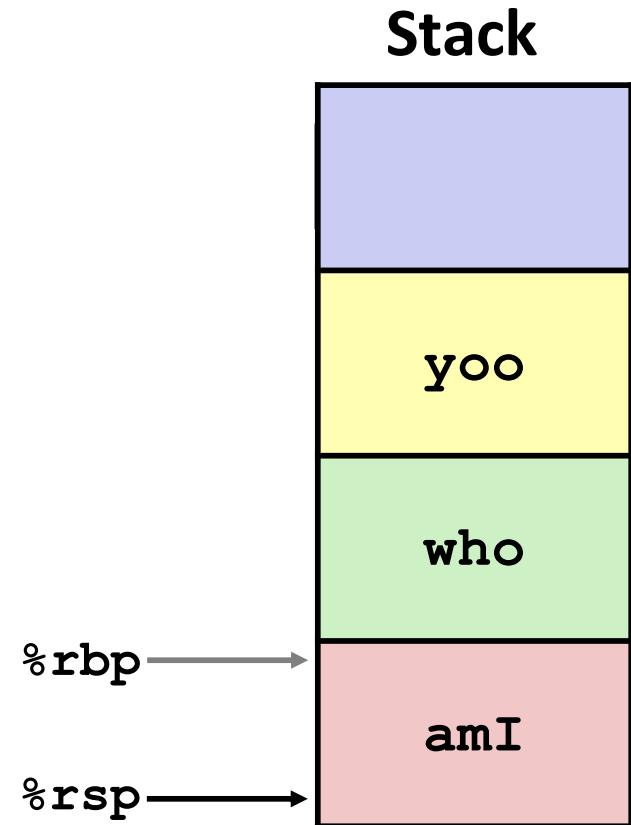

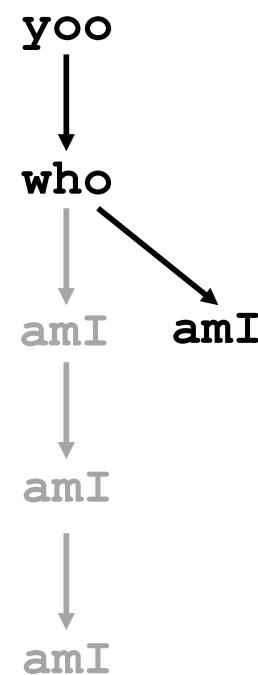

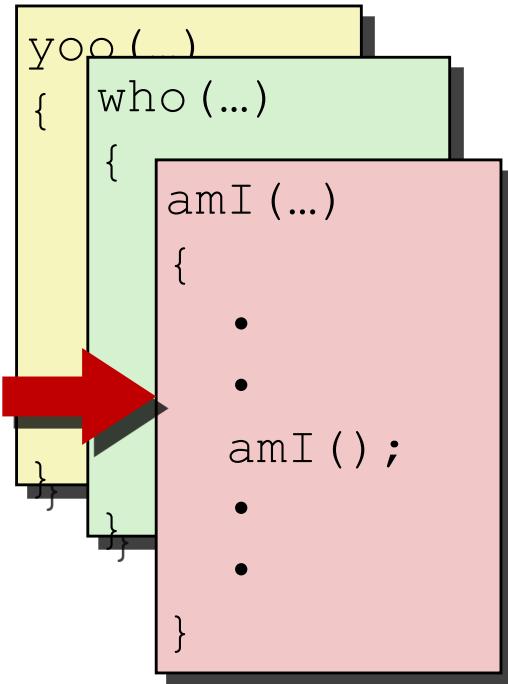

Example

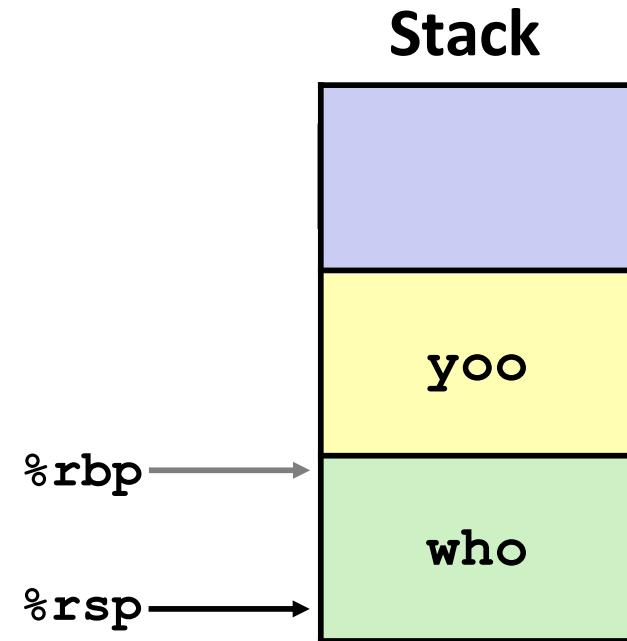

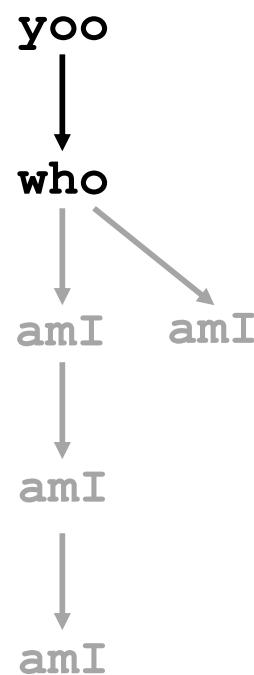

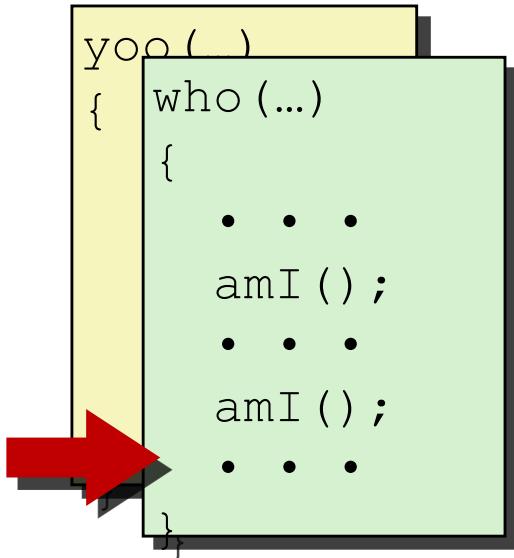

```
yoo( )  
{   who(...)  
{  
    . . .  
    amI();  
    . . .  
    amI();  
    . . .  
}
```

Example

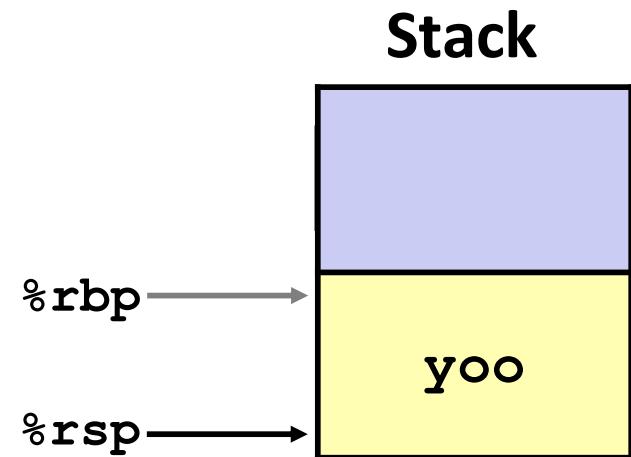

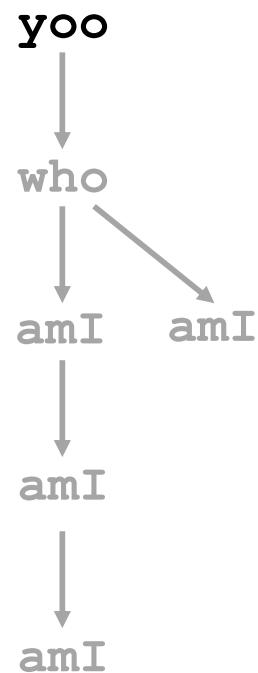

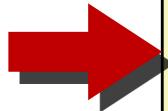

Example

Example

```
yoo (...)  
{  
    •  
    •  
    who () ;  
    •  
    •  
}  
}
```

x86-64/Linux Stack Frame

Current Stack Frame (“Top” to Bottom)

“Argument build:”

Parameters for function about to call

Local variables

If can't keep in registers

Saved register context

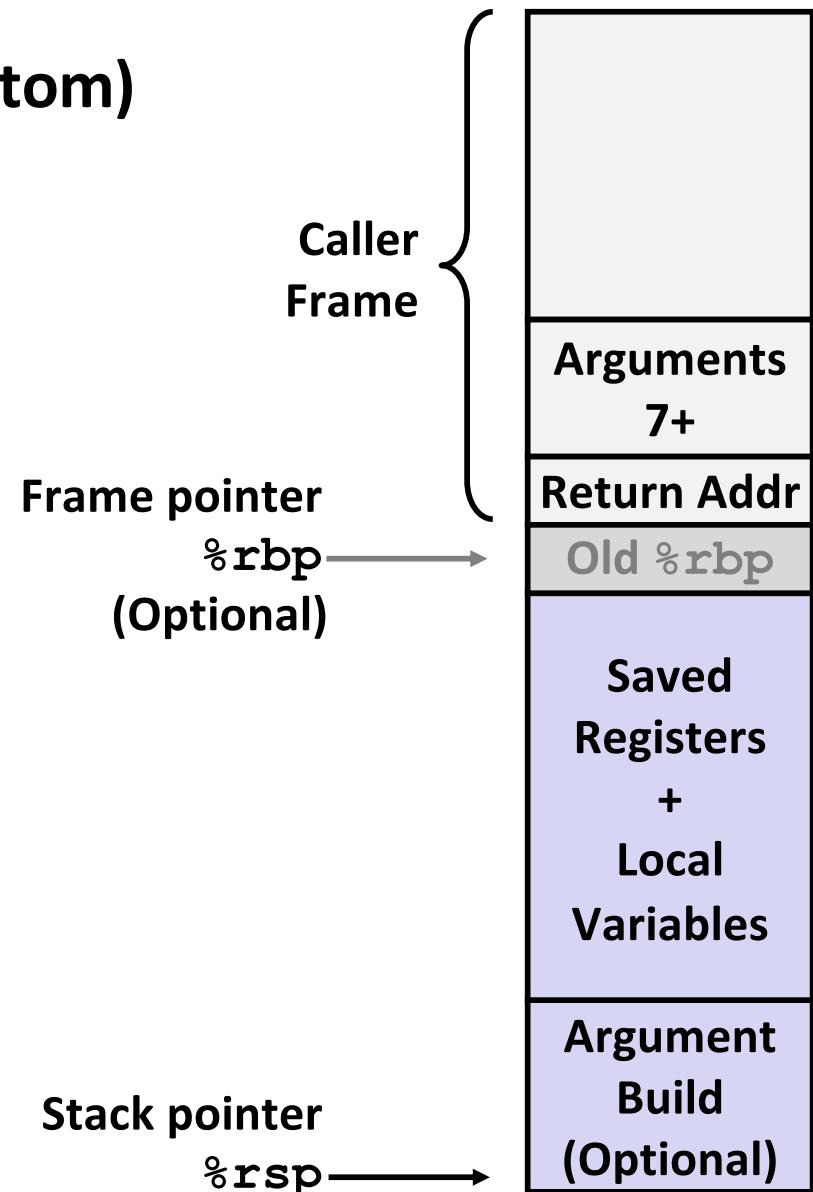

Old frame pointer (optional)

Caller Stack Frame

Return address

Pushed by **call** instruction

Arguments for this call

Register Saving Conventions

When procedure **yoo** calls **who**:

yoo is the *caller*

who is the *callee*

Can register be used for temporary storage?

yoo:

```
• • •  
movq $15213, %rdx  
call who  
addq %rdx, %rax  
• • •  
ret
```

who:

```
• • •  
subq $18213, %rdx  
• • •  
ret
```

Contents of register **%rdx** overwritten by **who**

This could be trouble → something should be done!

Need some coordination

Register Saving Conventions

When procedure **yoo** calls **who**:

yoo is the *caller*

who is the *callee*

Can register be used for temporary storage?

Conventions

“Caller Saved” (aka “Call-Clobbered”)

Caller saves temporary values in its frame before the call

“Callee Saved” (aka “Call-Preserved”)

Callee saves temporary values in its frame before using

Callee restores them before returning to caller

x86-64 Linux Register Usage #1

%rax

Return value

Also caller-saved

Can be modified by procedure

%rdi, ..., %r9

Arguments

Also caller-saved

Can be modified by procedure

%r10, %r11

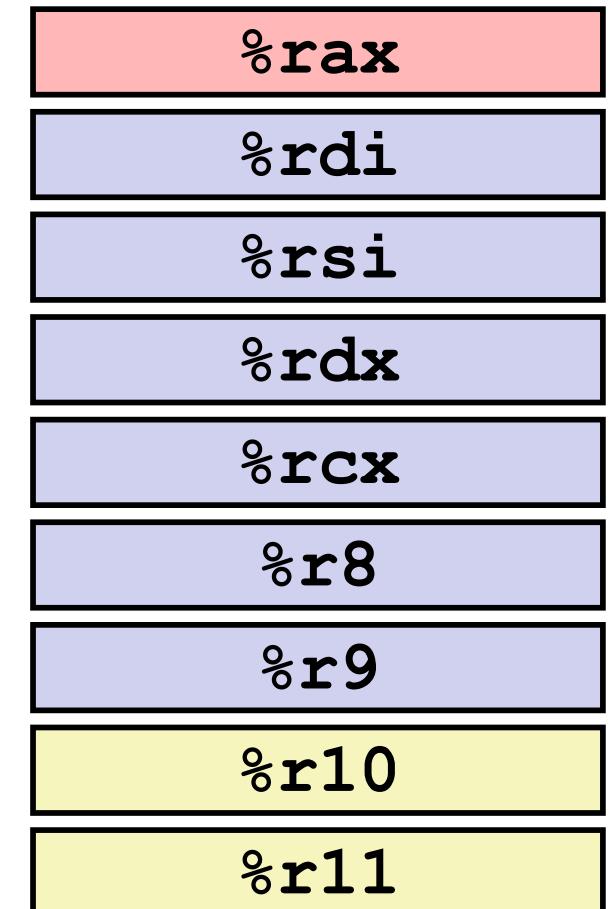

Caller-saved

Can be modified by procedure

Return
value

Arguments

Caller-saved
temporaries

x86-64 Linux Register Usage #2

%rbx, %r12, %r13, %r14

Callee-saved

Callee must save & restore

%rbp

Callee-saved

Callee must save & restore

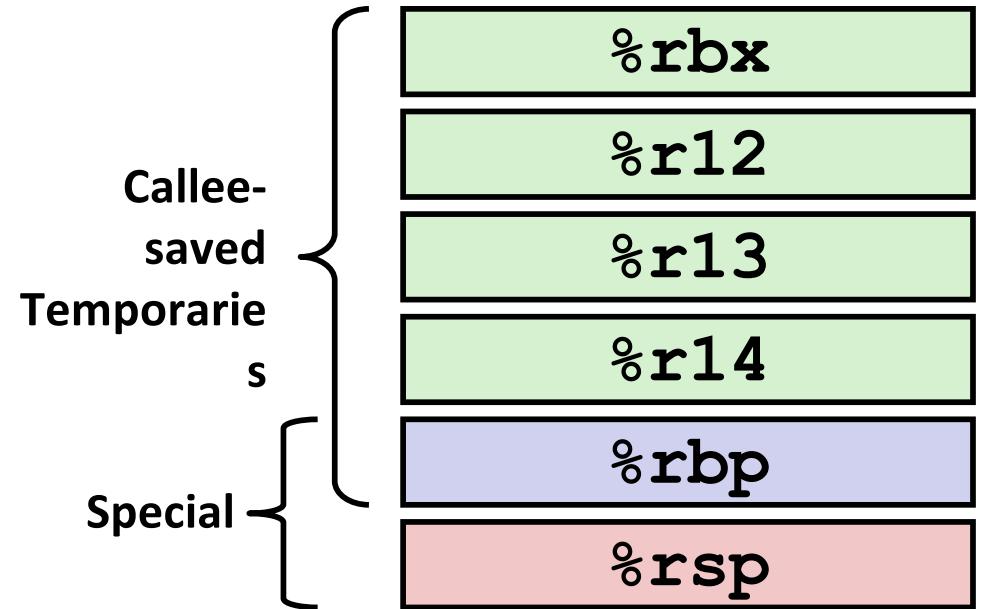

May be used as frame pointer

Can mix & match

%rsp

Special form of callee save

Restored to original value upon
exit from procedure

Summary : Mechanisms in Procedures

Passing control

- To beginning of procedure code
- Back to return point

Passing data

- Procedure arguments
- Return value

Memory management

- Allocate during procedure execution
- Deallocate upon return

Mechanisms all implemented with machine instructions

x86-64 implementation of a procedure uses only those mechanisms required

```
P (...) {  
    ·  
    ·  
    y = Q(x);  
    print(y)  
    ·  
}
```

```
int Q(int i)  
{  
    int t = 3*i;  
    int v[10];  
    ·  
    ·  
    return v[t];  
}
```

- Calling Conventions

- Passing control

- Passing data

- Managing local data

Arrays

- One-dimensional

- Multi-dimensional (nested)

- Multi-level

Structures

- Allocation

- Access

- Alignment

Reminder: Memory Organization

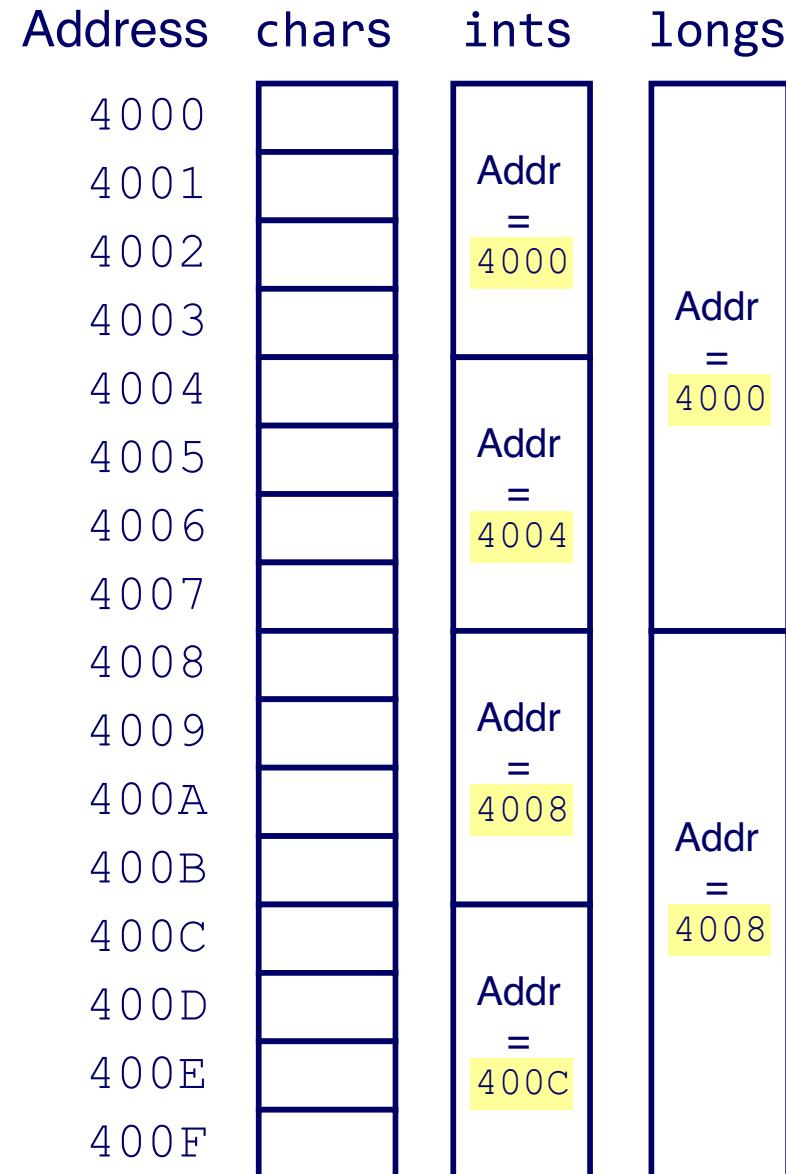

Memory locations do not have data types

Types are implicit in how machine instructions *use* memory

Addresses specify byte locations

Address of a larger datum is the address of its first byte

Addresses of successive items differ by the item's size

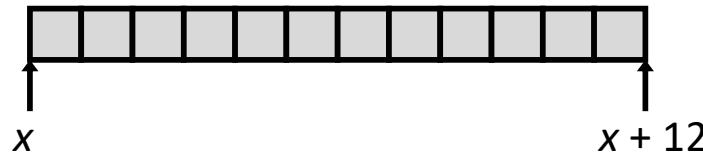

Array Allocation

C declaration **Type name [Length]** ;

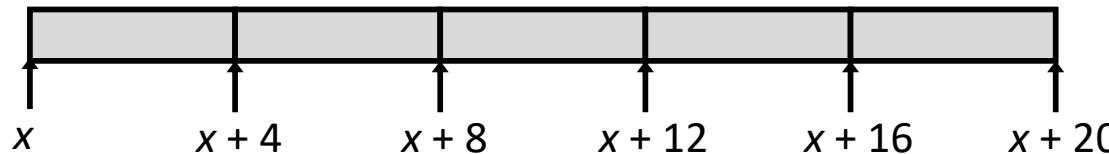

Array of data type *Type* and length *Length*

Contiguously allocated region of *Length* * **sizeof (Type)** bytes
in memory

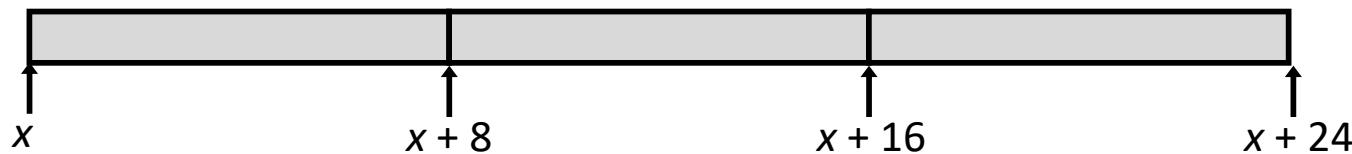

char string[12];

int val[5];

double a[3];

char *p[3];

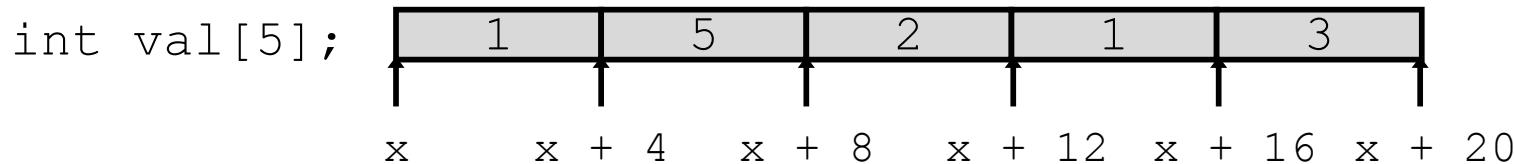

Array Access

C declaration **Type name[Length]** ;

Array of data type *Type* and length *Length*

Identifier **name** acts like¹ a pointer to array element 0

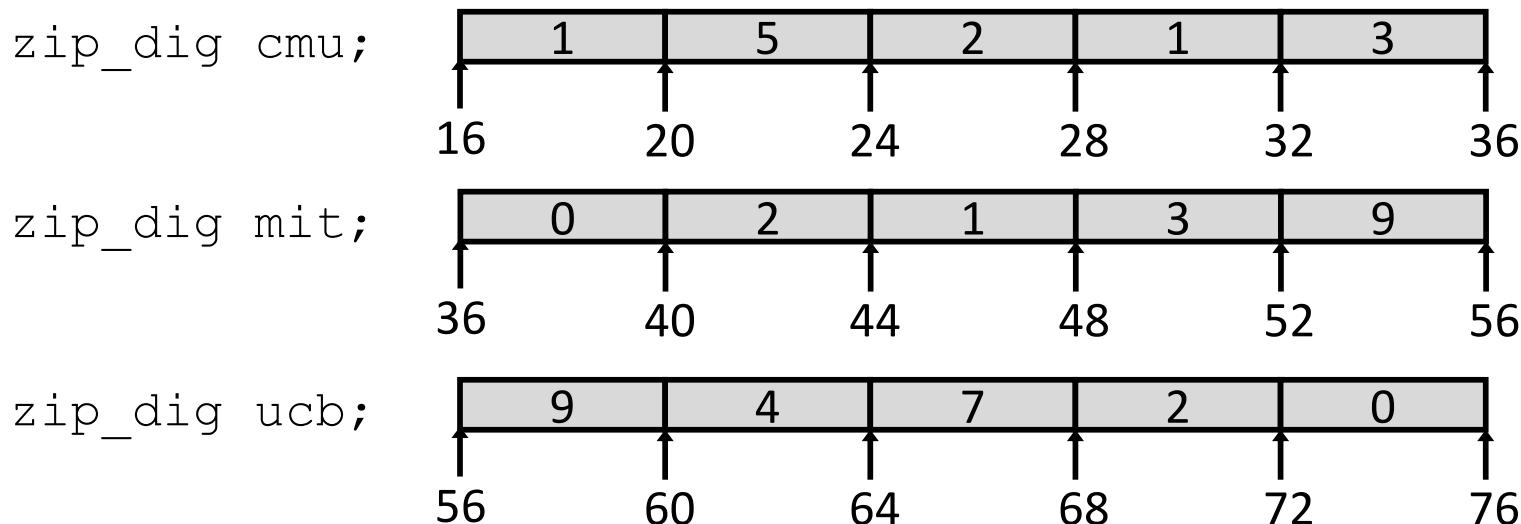

Expression	Type	Value	
<code>val[4]</code>	<code>int</code>	3	
<code>val[5]</code>	<code>int</code>	??	// access past end
<code>* (val+3)</code>	<code>int</code>	1	// same as <code>val[3]</code>
<code>val</code>	<code>int *</code>	<code>x</code>	
<code>val+1</code>	<code>int *</code>	<code>x + 4</code>	
<code>&val[2]</code>	<code>int *</code>	<code>x + 8</code>	// same as <code>val+2</code>
<code>val + i</code>	<code>int *</code>	<code>x + 4*i</code>	// same as <code>&val[i]</code>

¹ in most contexts (but not all)

Array Example

```
#define ZLEN 5
typedef int zip_dig[ZLEN];

zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

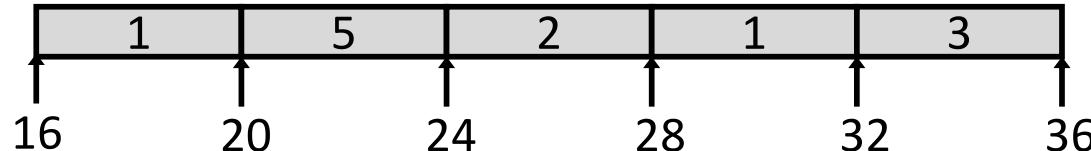

Declaration “`zip_dig cmu`” equivalent to “`int cmu[5]`”

Example arrays were allocated in successive 20 byte blocks

Not guaranteed to happen in general

Array Accessing Example

```
zip_dig cmu;
```

```
int get_digit  
    (zip_dig z, int digit)  
{  
    return z[digit];  
}
```

x86-64

```
# %rdi = z  
# %rsi = digit  
movl (%rdi,%rsi,4), %eax # z[digit]
```

- Register **%rdi** contains starting address of array
- Register **%rsi** contains array index
- Desired digit at **%rdi + 4*%rsi**
- Use memory reference **(%rdi,%rsi,4)**

Array Loop Example

```
void zincr(zip_dig z) {  
    size_t i;  
    for (i = 0; i < ZLEN; i++)  
        z[i]++;  
}
```

```
# %rdi = z  
movl    $0, %eax  
jmp     .L3  
.L4:  
    addl    $1, (%rdi,%rax,4)  
    addq    $1, %rax  
.L3:  
    cmpq    $4, %rax  
    jbe     .L4  
rep; ret
```

Array Loop Example

```
void zincr(zip_dig z) {  
    size_t i;  
    for (i = 0; i < ZLEN; i++)  
        z[i]++;  
}
```

```
# %rdi = z  
movl $0, %eax          # i = 0  
jmp .L3                # goto middle  
.L4:                  # loop:  
    addl $1, (%rdi,%rax,4) # z[i]++  
    addq $1, %rax          # i++  
.L3:                  # middle  
    cmpq $4, %rax          # i:4  
    jbe .L4                # if <=, goto loop  
rep; ret
```

Multidimensional (Nested) Arrays

Declaration

$T \text{ } A[R][C];$

2D array of data type T

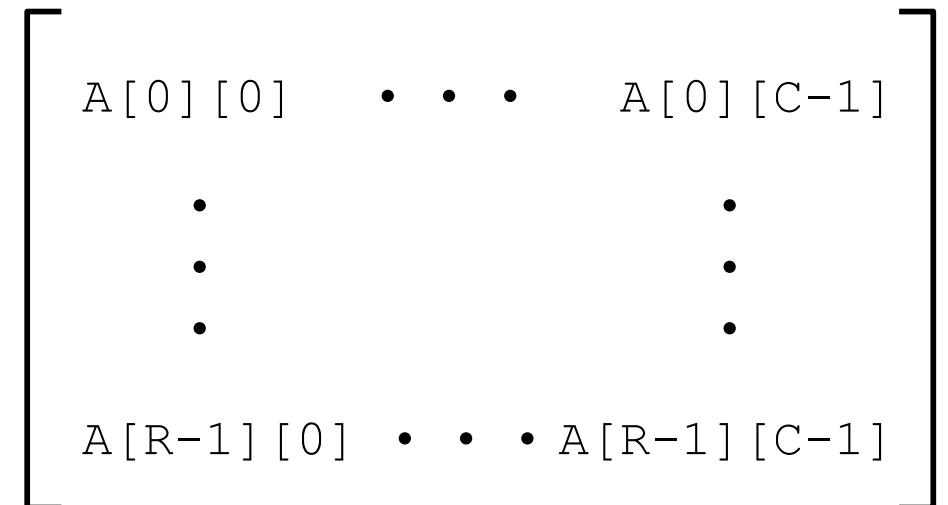

R rows, C columns

Array Size

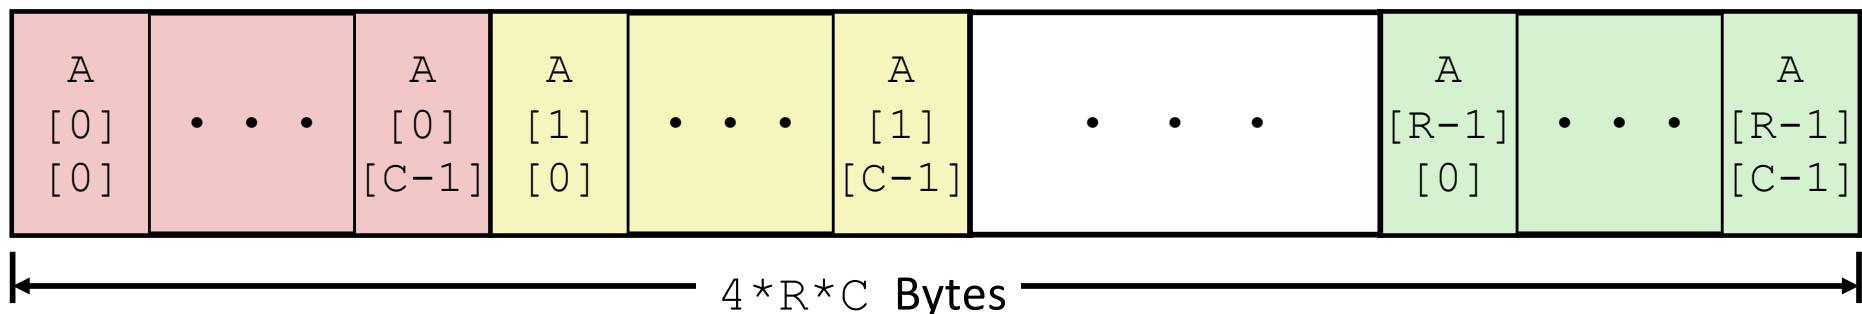

$R * C * \text{sizeof}(T)$ bytes

Arrangement

Row-Major Ordering

```
int A[R][C];
```

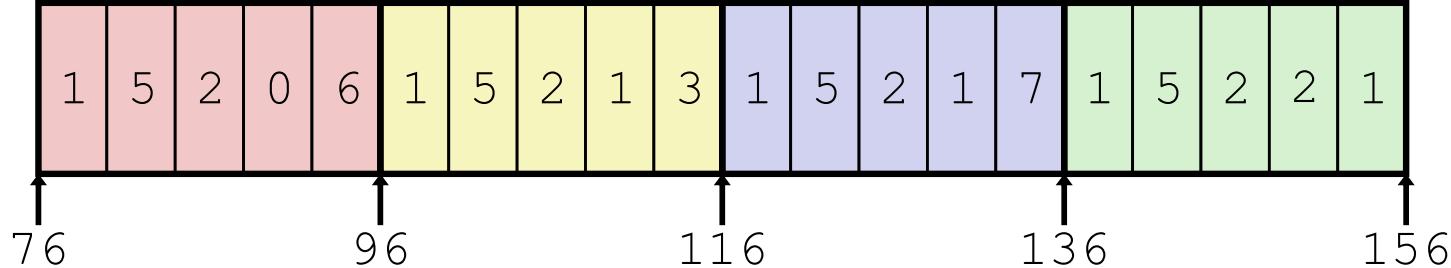

Nested Array Example

```
#define PCOUNT 4
typedef int zip_dig[5];

zip_dig pgh [ PCOUNT ] =
    {{1, 5, 2, 0, 6 },
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
```

zip_dig
pgh [4] ;

“zip_dig pgh[4]” equivalent to “int pgh[4][5]”

Variable **pgh**: array of 4 elements, allocated contiguously

Each element is an array of 5 **int**'s, allocated contiguously

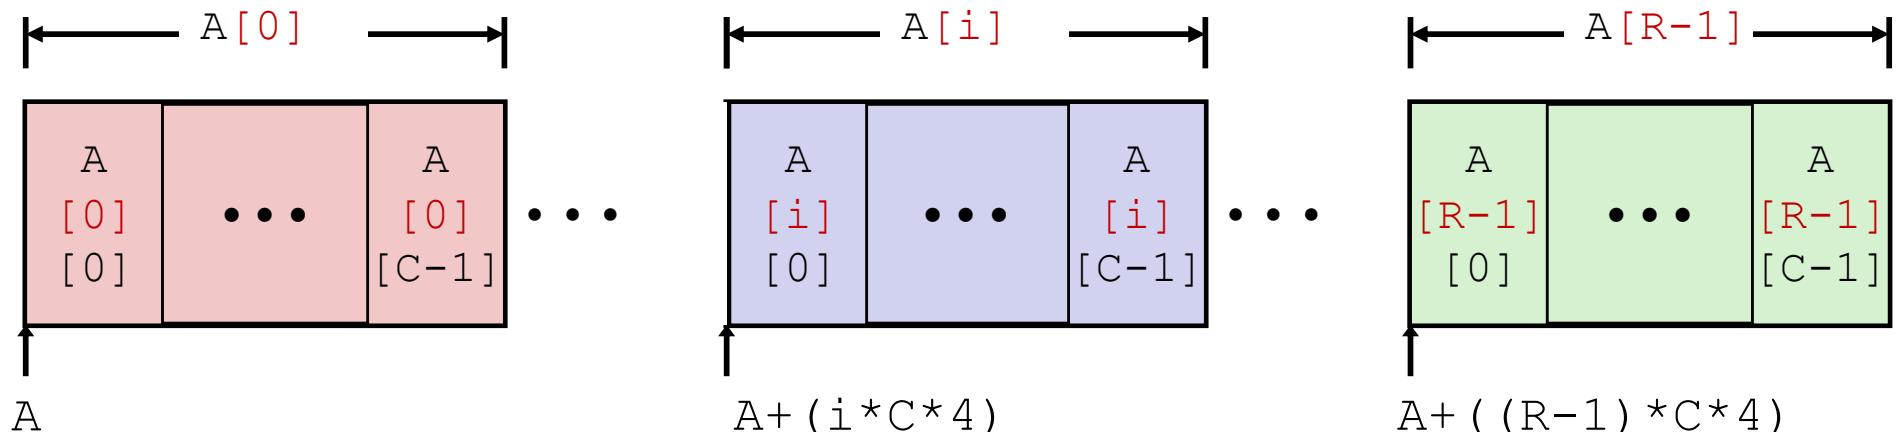

“Row-Major” ordering of all elements in memory

Nested Array Row Access

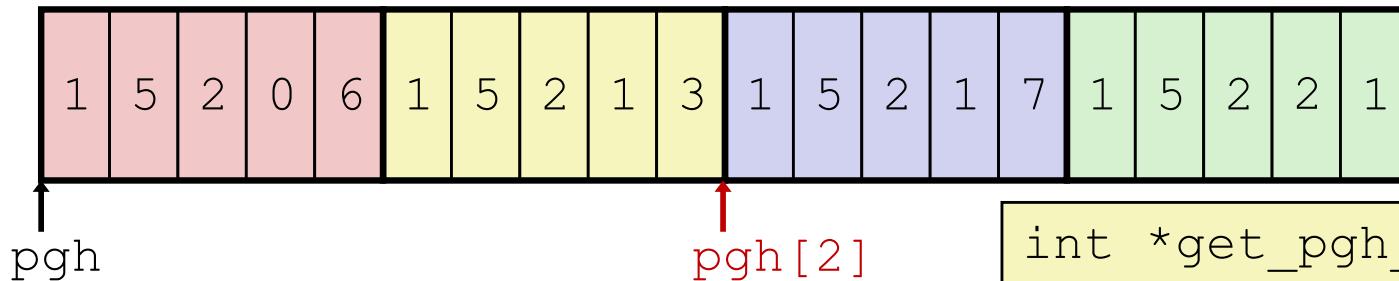

Row Vectors

- $A[i]$ is array of C elements of type T
Starting address $A + i * (C * \text{sizeof}(T))$

```
int A[R][C];
```

Nested Array Row Access Code

```
int *get_pgh_zip(int index)
{
    return pgh[index];
}
```

```
# %rdi = index
leaq (%rdi,%rdi,4),%rax # 5 * index
leaq pgh(,%rax,4),%rax # pgh + (20 * index)
```

Row Vector

- `pgh[index]` is array of 5 `int`'s
Starting address `pgh+20*index`

Machine Code

Computes and returns address

Compute as `pgh + 4*(index+4*index)`

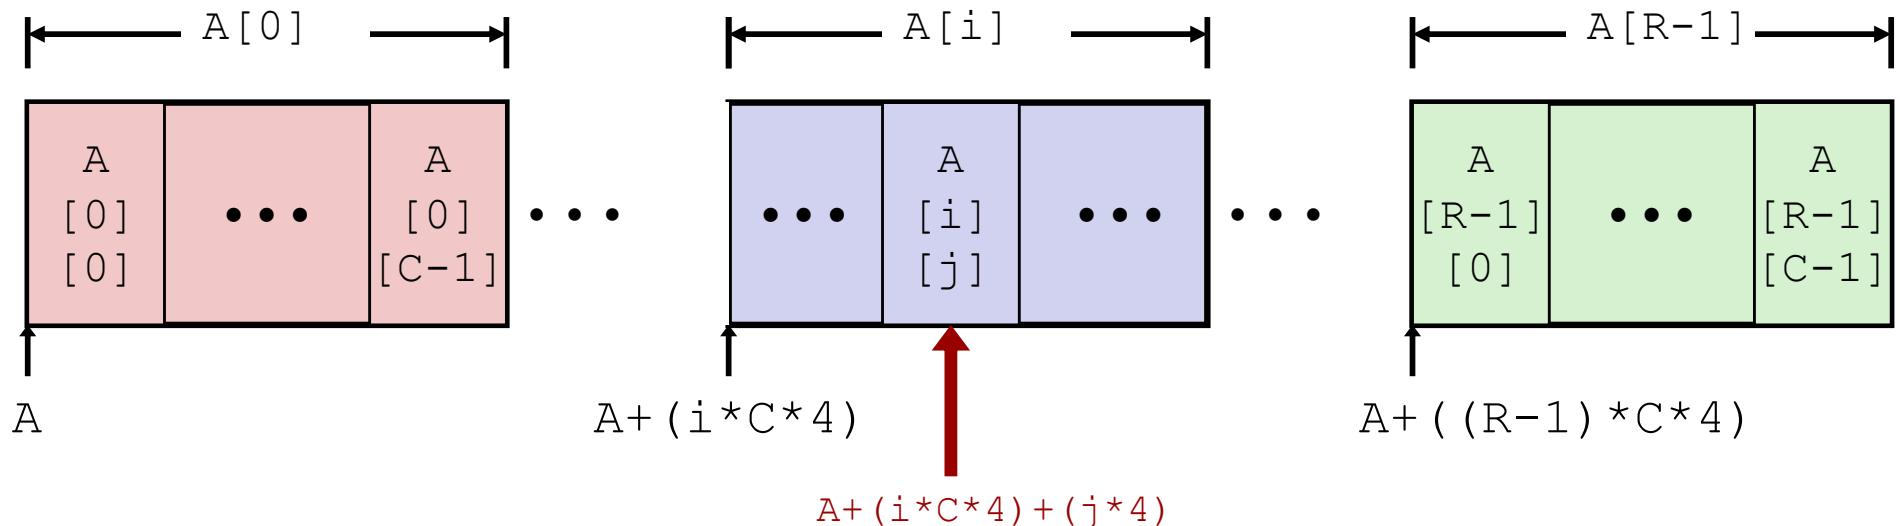

Nested Array Element Access

Array Elements

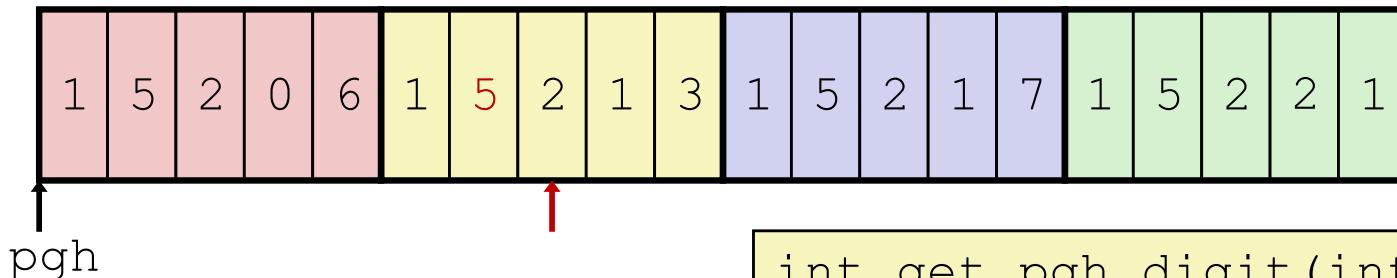

- $A[i][j]$ is element of type T , which requires K bytes

$$\begin{aligned} \text{Address } & A + i * (C * K) + j * K \\ & = A + (i * C + j) * K \end{aligned}$$

```
int A[R][C];
```

Nested Array Element Access Code

```
int get_pgh_digit(int index, int dig)
{
    return pgh[index][dig];
}
```

```
leaq (%rdi,%rdi,4), %rax      # 5*index
addl %rax, %rsi                # 5*index+dig
movl pgh(,%rsi,4), %eax       # M[pgh + 4*(5*index+dig)]
```

Array Elements

- **pgh[index][dig] is int**

Address: **pgh + 20*index + 4*dig**

$$= \text{pgh} + 4 * (5 * \text{index} + \text{dig})$$

Example: copy_element

```
#define M  
#define N  
  
int mat1[M][N];  
int mat2[N][M];  
int copy_element(int i, int j)  
{  
    mat1[i][j] = mat2[j][i];  
}
```

```
copy_element:  
    pushl %ebp  
    movl %esp,%ebp  
    pushl %ebx  
    movl 8(%ebp),%ecx  
    movl 12(%ebp),%ebx  
    movl %ecx,%edx  
    leal (%ebx,%ebx,8),%eax  
    sall $4,%edx  
    sall $2,%eax  
    subl %ecx,%edx  
    movl mat2(%eax,%ecx,4),%eax  
    sall $2,%edx  
    movl %eax,mat1(%edx,%ebx,4)  
    movl -4(%ebp),%ebx  
    movl %ebp,%esp  
    popl %ebp  
    ret
```

Example: copy_element

```
#define M 9
#define N 15

int mat1[M][N];
int mat2[N][M];
int copy_element(int i, int j)
{
    mat1[i][j] = mat2[j][i];
}
```

```
copy_element:
    pushl %ebp
    movl %esp,%ebp
    pushl %ebx
    movl 8(%ebp),%ecx
    movl 12(%ebp),%ebx
    movl %ecx,%edx
    leal (%ebx,%ebx,8),%eax
    sall $4,%edx
    sall $2,%eax
    subl %ecx,%edx
    movl mat2(%eax,%ecx,4),%eax
    sall $2,%edx
    movl %eax,mat1(%edx,%ebx,4)
    movl -4(%ebp),%ebx
    movl %ebp,%esp
    popl %ebp
    ret
```

Today

Procedures

- Stack Structure

- Calling Conventions

- Passing control

- Passing data

- Managing local data

Arrays

- One-dimensional

- Multi-dimensional (nested)

- Multi-level

Structures

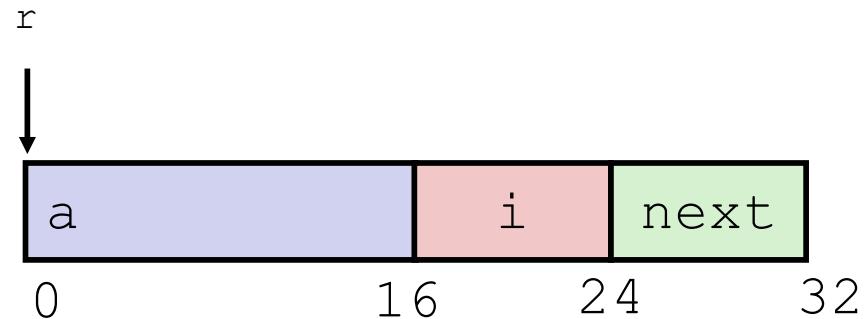

- Allocation

- Access

- Alignment

Structure Representation

```
struct rec {  
    int a[4];  
    size_t i;  
    struct rec *next;  
};
```

Structure represented as block of memory

Big enough to hold all the fields

Fields ordered according to declaration

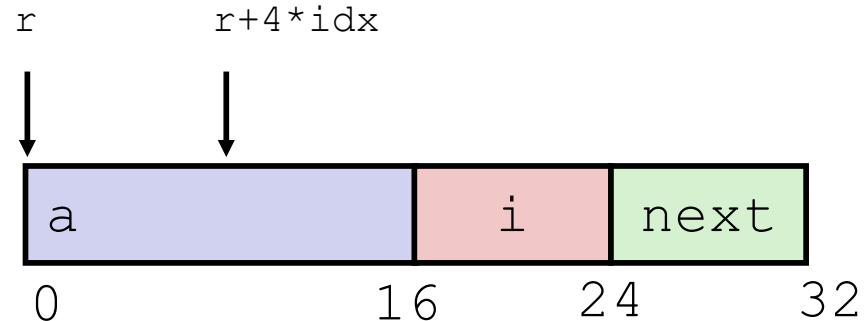

Even if another ordering could be more compact

Compiler determines overall size + positions of fields

In assembly, we see only offsets, not field names

Generating Pointer to Structure Member

```
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```

Generating Pointer to Array Element

Offset of each structure member determined at compile time

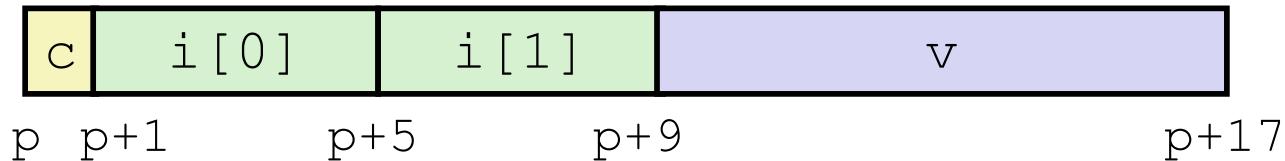

Compute as `r + 4*idx`

```
int *get_ap
(struct rec *r, size_t idx)
{
    return &r->a[idx];
}
```

```
# r in %rdi, idx in %rsi
leaq   (%rdi,%rsi,4), %rax
ret
```

Structures & Alignment

Unaligned Data

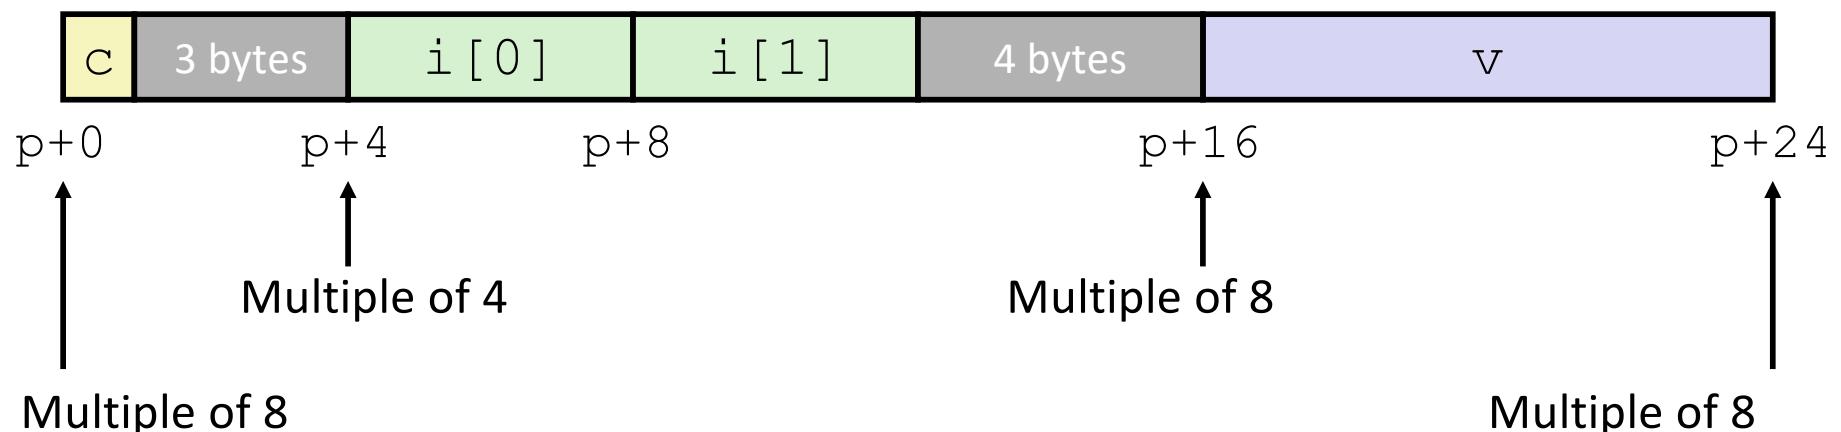

```
struct S1 {
    char c;
    int i[2];
    double v;
} *p;
```

Aligned Data

Primitive data type requires B bytes implies

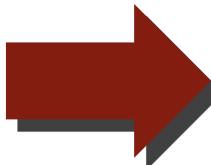

Address must be multiple of B

Saving Space

Put large data types first

```
struct S4 {  
    char c;  
    int i;  
    char d;  
} *p;
```

```
struct S5 {  
    int i;  
    char c;  
char d;  
} *p;
```

Effect (largest alignment requirement K=4)
